SECTION I

SECTION II

PREFACE

The 1972 Cook Inlet Annual Management report is divided into two main sections, each having a separate numbering system. The first Section (I) of the report gives a general overview on the Cook Inlet Management area and then deals specifically with the salmon gill net fishery of the Northern and Central districts of upper Cook Inlet. The second Section (II) presents information on lower Cook Inlet which includes the Southern, Outer, Kamishak, and Eastern districts. Statistics on the shellfish and herring fisheries as well as the salmon seine fishery appear in this second section of the report.

There is some overlap between the two sections of the report, for instance, the SUBSISTENCE FISHERY REPORT which appears in the Appendix of Section I, contains data on the lower as well as the upper Inlet. Also, some of the license statistics appearing in Section I and some of the salmon catch tables in the Appendix of Section I contain statistics on districts in both the upper and lower Inlet.

Data in this report supercedes information presented in previous management reports. Corrections or comments on the contents of this report should be directed to the area office at Homer.

ACKNOWLEDGEMENTS

The Cook Inlet Management staff during 1972 consisted of the following personnel:

Donald M. Stewart	Area Management Biologist	Jan. 1 - Aug. 15
Loren B. Flagg	Assistant Area Mgt. Biologist Area Management Biologist	Jan. 1 - Aug. 15 Aug. 16 - Dec. 31
David A. Daisy	Asst. Area Mgt. Biologist	Jan. 1 - Dec. 31
Charles Hurd	Asst. Area Mgt. Biologist	Oct. 16 - Dec. 31
Wilma Jones	Clerk Typist III	Jan. 1 - June 9
Jean Calhoun	Clerk Typist III	July 10 - Dec. 31
Hazel Vanderbrink	Fish Ticket Editor	April 17 - Nov. 14

The Cook Inlet Research staff during 1972 consisted of the following personnel:

Allen S. Davis	Salmon Project Leader	Jan. 1 - Dec. 31
Thomas Namtvedt	Assistant Project Leader	Jan. 1 - Dec. 31
Daniel Hennick	Shellfish Project Leader	Jan. 1 - Dec. 31

The Cook Inlet staff has much appreciated the support and capable leadership of their Regional Supervisors, Kenneth R. Middleton (Management) and Steven Pennoyer (Research). The staff would also like to acknowledge the many temporary employees who assisted with the various field projects in the Cook Inlet area. A list of these employees appears in the Appendix of Section I. The assistance of Bruce Barrett, Regional Fisheries Biologist assigned to the Central Region, was also appreciated for his work in Cook Inlet during the summer of 1972.

INTRODUCTION

Cook Inlet Management Area

The Cook Inlet area includes, in addition to Cook Inlet, those waters between Cape Douglas on the Alaska Peninsula and Cape Fairfield in Blying Sound east of Seward. Six fishing districts are described in the area: two in Cook Inlet north of Homer (the Northern and Central districts), two near the entrance which include the Kamishak Bay district on the Alaska Peninsula and Kachemak Bay on the Kenai Peninsula (the Southern district), and two bordering the eastern coast of the Kenai Peninsula (the Outer and Eastern districts). (Figure 1)

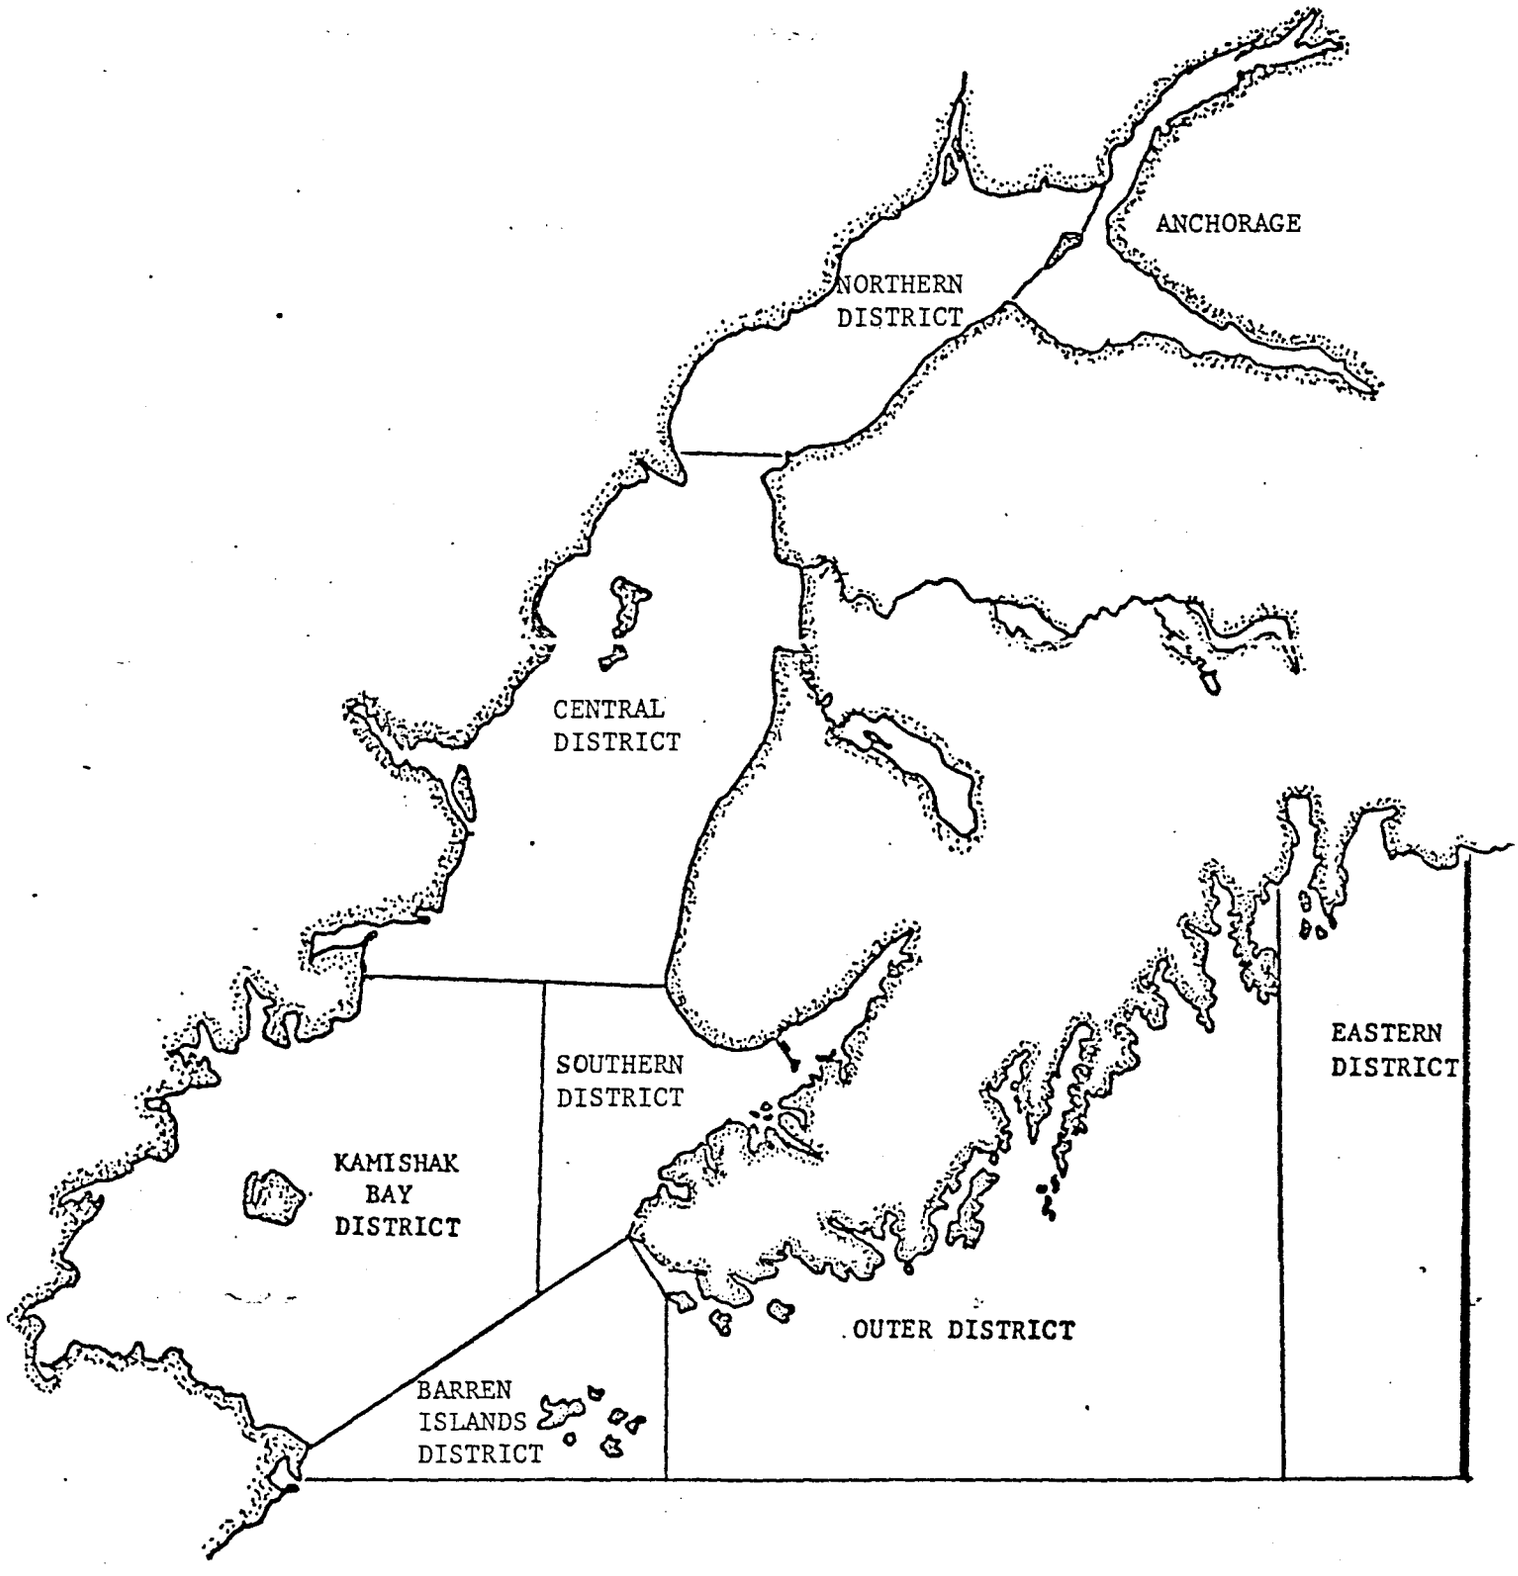
Salmon

Cook Inlet is characterized by exceeding strong tidal currents and, on occasion, strong winds. Most of the major salmon streams entering Cook Inlet are glacial; the waters north of Ninilchik are therefore very turbid and ideal for gill netting, although very little drift gill net effort occurred prior to 1947. Seining in these waters is impractical due to the currents. Set gill nets are successfully operated from shore or at anchored locations offshore. Traps were operated in the Inlet from 1897 until 1958. Outside of the Inlet seines are the principle gear used.

Salmon were first taken in the area in 1882 although no records of the number of fish harvested are available until 1893. Red salmon were the dominant species followed by lesser catches of kings and cohos in nearly equal numbers. Pink and chum salmon became important in the catch after 1912.

Figure 1

ALASKA DEPARTMENT OF FISH AND GAME
DIVISION OF COMMERCIAL FISHERIES
COOK INLET - RESURRECTION BAY AREA



The two districts in upper Cook Inlet (north of Anchor Point) are generally termed the gill net districts as only gill nets are permitted. Furthermore, only set gill nets are allowed in the Northern district where mobile gear has not been used since 1953. Primarily pink salmon are harvested in the Northern district, followed by reds and cohos. In the other gill net district, the Central, pinks and reds are taken in roughly equal proportions. King salmon have been an important species in the gill net districts but, due to their decline from earlier years, have been protected by late opening dates since 1964.

The bulk of the salmon caught in the gill net districts are typically taken during a relatively brief time. As the major salmon streams entering the Inlet are silty, escapement enumeration is nearly impossible. Escapement estimates are in part based upon the size of the commercial catch, upon test fishing at or near the major stream mouths, and more recently with the aid of sonar counting devices.

Salmon move through the Central district in a generally predictable pattern. Chum salmon are rarely caught on the east side beaches, for example. Some tide rips, up which salmon move in some concentrations, harbor more red salmon than chums, and vice versa.

All five species of salmon may be found in the district simultaneously, but each species has a normal period of greatest abundance. The early kings can be expected in late May. Early red salmon (locally called "bluebacks") bound for Kasilof and Kenai rivers and apparently for some minor systems along the east and west sides of Cook Inlet, appear in early June and run until the third week of that month.

Shortly after June 25 red salmon increase rapidly, reaching a peak in abundance usually between about July 18 and 22. The red salmon are followed by the chums, and the chum run peaks within a very few days of the peak of the red run. In years of great abundance of pinks, they are found in large numbers from about July 18 until after July 25; during some years pinks continue to arrive in strength starting the first week of August on the east side beaches bound for the Kenai and Kasilof rivers.

Coho salmon peak in late July in the district, and this species continues to appear in decreasing numbers throughout the fall months. Fresh run fish of this species may be found in the Central district as late as December.

The proportion of catch varies between set net and drift gear, depending largely upon weather, tides, and the species of fish involved. In years when strong southwesterly winds and large tides occur, red salmon bound for the Kenai and Kasilof rivers are pushed onto the beach and/or into the Northern district from whence they follow the beaches attempting to find their home streams; at such times the set net gear on the east side beaches make large catches, and drift catches fall off.

Strong tidal action along beaches of much of the Central district makes it difficult for fishermen to anchor set nets offshore. However, a few locations on the east side beaches between Ninilchik and Cape Kasilof permit use of offshore nets.

During a normal season drift fishermen usually start fishing east of Chisik Island, and as the season progresses, they move east and north, following concentrations of fish, until the latter part of the run, the bulk of drift fishing boats are almost wholly within the northern portion of

the Central district, east of Kalgin Island. Many drifters find it worthwhile to drift as far north as the Boulder Point boundary which separates the Northern from the Central district.

The Southern district, which includes Kachemak Bay, yields primarily pink salmon although other species are harvested. Set net fishermen of this district catch most of the red salmon taken there, while the seiners rely mostly upon pinks and chums. Some of the reds taken here are bound for streams farther up the Inlet. Pinks are bound mostly for the clear water drainages within the district.

The Kamishak Bay district is a difficult area in which to travel, much less fish, and few fishermen are willing to venture into the area for salmon. Cannery operators are reluctant to provide tender service for fishermen in the area when tenders can be used to haul fish from other districts. Hand purse seines and beach seines are the only legal gear. This district is unquestionably the most difficult of the seven within the management area to fish for salmon. At least half of a fisherman's time is spent awaiting weather. Because of the light fishing pressure, and the constant weather problem a seven-day-a-week fishing period has been provided within this district for the past several years. Pinks and chums provide the bulk of the catch.

The Outer district includes that stretch of coastline from Point Adam, at the very southwest tip of the Kenai Peninsula, to the latitude of Bear Glacier, which is adjacent to Resurrection Bay. This is an area of many fiord-like bays and short, often precipitous streams, some of which are glacier fed. Hand purse seines and beach seines are the only types of salmon gear allowed, however, most of the seine fishermen who license in Cook Inlet fish part of each season in the Outer district. Pinks and chums are the chief species harvested.

Because the highly productive streams are clear, and salmon may be observed during aerial surveys, the Outer district lends itself to relatively intensive management methods. When spawning escapement is judged sufficient, surplus fish can be harvested; when escapement is weak, the area can be closed to fishing.

The Eastern district is the least important commercial salmon producing district in the management area; it extends from the latitude of Bear Glacier (where it adjoins the Outer district), includes all of Resurrection Bay and Day Harbor, and ends at the latitude of Cape Fairfield, which is the eastern-most boundary of the management area. There are few streams within the district, and these produce mainly pink, chum and coho salmon.

Gear levels in Cook Inlet have increased dramatically in recent years. Drift gill net registration totalled 288 in 1960 (75% residents). By 1970, the number of drift licenses reached 757, of which about 30% were non-residents. Set gill net licenses also increased but less dramatically - 570 in 1960 and 772 in 1970. About 92% of the set netters are residents. During the same period, purse seine registration fluctuated between 58 in 1967 and 112 in 1963, 95% residents.

Since 1952 salmon fishing during the major part of the run has usually been held to two 24-hour fishing periods a week. If more fishing time were allowed with the present level of gear efficiency there would be a very real danger that the all-important spawning escapement would not be achieved. There is so much gear in the gill net fishery that it is conceivable that during any 24-hour fishing period, usual circumstances could combine to allow a catch that could be damaging to the future of the fishery -- and the

evidence of this happening would not be available until after such a catch was made.

Premised upon strigent gear restrictions, which include the prohibition of power blocks to retrieve seine gear, and considering the known level of gear efficiency, open fishing periods or areas are established in two ways in the Cook Inlet area. In the Southern, Outer and Kamishak Bay districts where escapement can be observed from low flying aircraft, fishing is based on observed escapement. In the gill net fishery in the silty portion of the Inlet, where all major drainages are turbid, visual enumeration of salmon escapement is impossible. During the normal several-week buildup to a peak of this fishery, a trend and a measure of strength of the run can generally be obtained by comparative catches by species, by date, as a method of management. In essence, the entire fishery is acting as a test fishery; i.e., sampling the strength of the run.

Management of the salmon fisheries, using comparisons with past catches, plus data provided by test fishing and counting towers, obviously has many drawbacks. However, it does have the advantage of providing information immediately, at the time the fishery is active, and at a time when liberalization or restriction of the fishery can be of benefit.

Shellfish

King crab, tanner crab, dungeness crab and shrimp are harvested commercially in the Southern, Outer, Kamishak and Eastern districts of Cook Inlet. There is virtually no fishing for these species north of Anchor Point. King crab is most important to the area and the catch has averaged about 4.6 million pounds since 1960. The Board of Fish and Game established a seasonal quota in 1969 of 4.5 million pounds in an attempt to stabilize annual fluctuations in the catch and maintain a healthy stock of all age classes.

The quota was increased for the 1972 season to 5.5 million pounds on the strength of stocks in the Kamishak and Barren Island districts.

Tanner crab were first fished commercially in 1968 and since then the fishery has developed very rapidly with the 1972 catch exceeding 4 million pounds. Effort in the early years of the fishery was concentrated in Kachemak Bay, however, the fishery has recently expanded to the Kamishak Bay and Eastern districts. Continued expansion of this fishery is expected and regulation controls will be needed in the near future.

There was an active trawl fishery for shrimp in Cook Inlet during the early sixties before the earthquake destroyed processing facilities in Seldovia and Seward. Five years elapsed before any significant effort in this fishery resumed in 1969. The present trawl fishery is located primarily in Kachemak Bay and is regulated by a 5 million pound seasonal quota. There is also a limited pot fishery in Kachemak Bay and this fishery is presently expanding as market conditions improve.

Other Species

The only other significant fishery in Cook Inlet at the present time is the herring fishery, primarily directed at sac roe. This fishery has developed since 1969 and fishing effort has been concentrated in Resurrection and Kachemak Bays. The drop in catch and effort in this fishery during the last two years is related both to market problems and harsh environmental conditions.

1972 SEASON SUMMARY

Salmon Fishery

The 1972 commercial salmon catch for Cook Inlet totaled 2,399,996 fish which was the lowest recorded even-year harvest since 1930. The catch was comprised of 16,174 kings (.67%), 937,721 sockeye (39.07%), 83,167 cohos (3.47%), 657,243 pinks (27.39%), and 705,691 chums (29.40%). (Table 1)

The Central district contributed by far the largest share of the catch with 2,014,966 total salmon (83.96%). The Northern district had the second largest catch with 220,605 salmon (9.19%) followed by the Outer district with 70,942 salmon (2.96%), Southern district with 46,759 salmon (1.94%), Kamishak district with 26,794 salmon (1.12%) and finally the Eastern district with 19,930 salmon (.83%).

The drift gill net catch accounted for 1,208,262 salmon (50.34%), set nets took 1,064,551 salmon (44.36%), seines 126,271 salmon (5.26%) and troll gear accounted for 912 salmon (.04%).

Salmon gear registrations for 1972 totaled 1,368, down from the all time high in 1970 of 1,643 registrations, (Table 2). The greatest reduction was in the drift gill net gear category as there were only 571 registrations in 1972 compared to 710 in 1971 and 757 in 1970. The decrease in registrations is most likely due to the three successive poor red salmon runs experienced in Cook Inlet (1969-1971). Of the total 1972 registrations for all salmon gear 86 percent were residents and 14 percent nonresidents.

Shellfish Fishery

This section is presented as an overview of the Cook Inlet shellfisheries. Detailed data tables are presented in the sections for specific management units.

The 1972 shrimp harvest of 5.5 million pounds was the second greatest on record. The catch for 1971 was 5.4 million pounds and for 1970, the record year, it was 5.8 million pounds. In past years the trawl fishery accounted for over 99 percent of the total shrimp catches. A record catch of 171 thousand pounds of pot caught shrimp in 1972 accounted for three percent of the total catch. Pot catches were 53 thousand pounds in 1971 and 9 thousand pounds in 1970.

The 1972 Cook Inlet king crab harvest of 4.6 million pounds exceeded the 1971 catch by one-half million pounds and was the highest on record since 1964. The Southern district, which includes the Kachemak Bay area accounted for 1.9 million pounds and the total for all other districts was 2.7 million pounds.

The total catch of tanner crabs during 1972 amounted to 4.8 million pounds which was the highest on record since the fishery developed. This large catch was due to an increased effort as 1,098 landings were made compared to 613 landings in 1971. The major part of the catch 2.9 million pounds, was taken in the Southern district, 1.2 million pounds were taken in the Kamishak district, and for the first time a substantial effort in the Eastern and Outer districts yielded over 700 thousand pounds.

The total 1972 Dungeness crab harvest in Cook Inlet was 38,930 pounds all from the Southern district. This was less than half the 1971 catch of 96,846 pounds. The 1970 harvest was 208,577 pounds. Lack of market interest and effort were the basic reasons for this low catch figure.

The 1972 razor clam harvest, all from the Polly Creek area in the Central district was 31,360 pounds in the shell. A dredge operation accounted for 806 pounds of this total, the balance was harvested by hand operated shovels. In 1971 the harvest was 14,755 pounds.

Herring Fishery

The 1972 herring roe fishery in the Cook Inlet Management Area was a failure for the second year in a row. The total catch for the area was 96 tons with 95 tons harvested from Resurrection Bay in the Eastern district and 1 ton from Kachemak Bay in the Southern district. This fishery is discussed in detail in Section II of this report.

SALMON FISHERY

Northern district

The Fishery: In addition to the regular fishing time the Northern district was allotted two early 12-hour periods, one on June 5 and the other on June 12, to test the strength of the king salmon run. The gill net mesh size for these two periods only was set at seven inches minimum. The normal allowable mesh size is six inches maximum.

The early two king periods were very much a disappointment. A total of 3,700 kings were taken during these two periods which was 25 percent below the harvest taken in the 1971 test fishery. In addition king catches at the Susitna Station test fish site on the Susitna River were poor. Since the two 12-hour periods and test fishing indicated a weak run, the next scheduled period on June 19 was closed. The next open period on June 23 was cut to six hours with fishing time set on the ebb in a further attempt to hold down the harvest.

Fishing time returned to the normal two 12-hour periods per week on June 26 and no further adjustments were made in the district until July 26 when an additional 12-hour period was allowed. Sockeye escapement in the Northern district, with the exception of Fish Creek, appeared quite good and additional time was warranted. The catch of other species up to this time was very disappointing. Pink catches were running about half of what was expected and coho and chums were down also. The catch peaked out

in the Northern district on July 28 when 56,000 salmon were taken. Catches on the next period (July 31) fell sharply, indicating that the bulk of the salmon were through the district. On August 2, the Northern district, along with the rest of the gill net area, was given one additional 12-hour period per week for the remainder of the season since sockeye escapement was satisfactory and effort had fallen off. Table 3 shows the 1972 catch by period for the district.

The Northern district catch since 1954 is presented in Table 4. The 1972 catch of 220,605 salmon was about ten percent of the gill net area catch and nine percent of the total Cook Inlet catch. The 1972 catch was 64 percent below the average even-year catch since 1954, making it the lowest even-year catch during that time. It should be noted that 1972 was the first even-year with only 24 hours per week base fishing time. In 1969 and 1970 base fishing time was 36 hours per week and prior to 1969 fishing time was 48 hours per week. The reduced fishing time since 1968 has definitely had the effect of reducing the catch for all species of salmon.

A total of 4,912 kings were harvested in 1972 which was 41 percent below the 19-year average and about one-half of the 1971 catch.

The sockeye catch of 85,737 was about 12 percent below the 19-year average. Considering the amount of time fished, the catch seemed to indicate a normal run.

Coho salmon are predominantly four-year fish in the Inlet and tend to run in greatest strength on even years. The 1972 catch of 19,346 cohos was 83 percent below the even-year average since 1954 being by far the lowest coho catch for any year since that time. Since coho escapement was

poor even in areas where no commercial fishery was held, the commercial fishing probably had little to do with the decline. It appears that natural conditions such as adverse spawning and/or rearing conditions or above average ocean mortality are the main causes. The even-year coho stocks, as judged by catch, were in a very healthy condition as recently as 1968, which coincidentally was the last year two 24-hour periods were fished during the main season and five 24-hour periods per week were fished after the main run. It appears that coho catches are more directly related to fishing time than catches of other species. This may be due to the fact that the coho run is spread over a longer period of time and that cohos run through all parts of the Inlet to just about every anadromous stream. In other words they are more evenly distributed than other species in both timing and area of occurrence. This in turn makes them less susceptable to a heavy harvest during infrequent and short fishing periods.

Pink salmon are exclusively two year fish and like coho run in greatest strength on even years. The 1972 catch of 90,830 was extremely poor for pinks in fact the lowest even-year catch since 1954. The 1972 catch was 75 percent below the even-year average.

The Northern district chum catch since 1969 has averaged about 17,000. The 1972 catch of 19,780 falls just above that average, however, it is about 70 percent below the average since 1954. The Susitna River which empties into the Northern district is thought to account for about 80 percent of the chum production. Most of the chums produced in the Susitna are taken in the Central district drift net fishery. Since this fishery has not experienced the same decline in catches as the Northern district,

it would appear that the poor chum catches in the Northern district are the result of a reduced fishing time rather than a reduction in the run size. The point should be made for the Northern district that it is a set net fishery only and thus much less efficient than the Central district. Because of the tremendous tidal fluctuations in the area the tide stage fished is critical in the set net operation. With 12-hour periods, there is sometimes only one or two hours during the period when nets are fishing inefficiently. Another factor in analyzing recent Northern district catches is the reduction in gear in this area. (See Table 5)

Field Operations

Effort Surveys: Aerial surveys of the fishery were made periodically during the season in order to assess the amount of gear in use. Surveys began with the first king salmon test period on June 5 and ended on July 31. A total of seven surveys were flown. Table 6 lists each survey by date broken down by section of beach. The lowest effort of the season was on June 26 with 101 nets fishing and the highest recorded effort was on July 28 with 230 nets fishing. Table 5 gives the high, low and mean effort per year since 1963. Effort in 1972 was 18 percent below the average since 1966 and was the lowest effort recorded since surveys were started in the early 60's. There are two basic reasons for this: (1) The drift fishery in the Central district has developed to the point where it is harvesting a much larger percentage of Northern district bound fish thus leaving less fish for Northern district set netters to harvest. This has caused some fishermen to drop entirely out of the fishery while others have simply

resorted to fishing less gear. (2) Because of the short 12-hour fishing periods, most fishermen have found it impossible to fish a full complement of gear on certain tides. With 24-hour periods fishermen could always count on fishing a complete tidal range, however, with 12-hour periods sometimes the best stage of tide for a certain site or net location does not occur within the period.

Susitna Station: The sampling site at Susitna station, located just below the confluence of the Susitna and Yenta Rivers, was operated again in 1972. This was the fourth year of operation at this site. The site was established to provide an index of salmon run timing and species composition plus A.W.L. data. In addition observations were made on air and water temperatures, river level and sky cover.

Salmon were captured with a fishwheel and gill nets. The four basket fishwheel was operated from May 28 to August 4. The wheel was generally fished daily from 0830 to 2030. On a catch per unit of effort basis, sockeye fishwheel catches in 1972 exceeded the 1970 level but were below the 1971 level. Pink salmon fishwheel catches were less than 1970, the parent year. The fishwheel caught a total of only 37 king salmon which compares to 86 in 1971 and 161 in 1970. (Table 7)

Set gill netting was conducted daily at two locations in the river for approximately one hour at each site. All gear was 12 feet in depth but varied from 25 feet to 60 feet in length and 4 7/8 inches to 7 inches in mesh size. The gill netting provided additional information on timing and A.W.L. relationships.

Talachulitna Tower: The Talachulitna River is a major salmon producing system in the Susitna Basin. In past years runs of pinks have been estimated at one million and runs of sockeye have reached fifty thousand. In addition, chum, coho, and king salmon also use the system extensively. In view of this, it was decided to enumerate the various runs into the Talachulitna and since the river was too large for a weir, counting towers were utilized.

Table 8 gives the expanded total daily count by species for 1972. An estimated 232,287 salmon passed into the Talachulitna while the towers were in operation. The total number of salmon enumerated is reasonably accurate; however, there is some question as to the accuracy of the species breakdown since difficulty was enountered in separating between chum and sockeye salmon.

Fish Creek: The Fish Creek that drains Big Lake and empties into Knik Arm has been continuously enumerated for salmon since 1936. Table 9 shows the dates of operation, the count by species, and the method of enumeration for each year from 1936 to 1972. This year the weir was operated until September 8 which was late enough to allow the total escapement of all species to be documented.

The sockeye escapement of 6,981 was the second lowest ever recorded approaching the all-time low of 6,242 in 1969. In addition to sockeye, 709 coho, 57 pink, 2 kings and 1 chum were counted through the weir.

The pink run, which is a stock with a predominant even-year cycle, showed a marked decline. The parent stock, 170, numbered 3,940. The

1/ Rating of Poor, Fair, or good given only.

2/ Includes estimated 3,500 sockeye salmon still behind weir when it washed out 8/8/70.

3/ Includes estimated 500 sockeye salmon still behind weir when it was removed 8/7/71.

greatest recorded run of pinks occurred in 1968 when 48,128 were counted through by July 31. This extremely small run of pinks (57) most likely stems from the severity of environmental conditions in the winter of 1970-71.

The coho run this year was also considerably below historic levels. In 1968, the parent year for the 1972 coho run, 2,088 were counted through July 31. The low water conditions present in 1968 may well be the primary cause of the failure of the 1972 coho run into Fish Creek.

Escapement Surveys: Previous escapement surveys in the Northern district, with the exception of king salmon surveys, have been performed on a very irregular basis. In view of the large percentage of the gill net area spawning systems that are located in the Northern district, an indexing system of the various spawning areas was initiated in 1972. Forty-nine index areas were established in the Northern district, 22 of which had been established by the U. S. Fish and Wildlife Service prior to statehood. The initial emphasis was on red salmon.

Surveys were made by air, boat, or on foot, aerial surveys were conducted with a PA-18 supercub, and Bell G4A and Jet Ranger helicopters. Boat surveys were conducted from an Avon inflatable rubber boat. Surveys began on July 20 and ended on September 16, which encompasses the peak of spawning for most of the area.

Of the 40 areas surveyed 22 were selected as being representative of the Northern district. The peak count for these index areas is given in Table 10. A comparison of this data with previous years is difficult due to inadequate survey coverage in previous years.

King salmon escapement surveys in the Northern district were conducted by the Sport Fish Division again in 1972. Table 11 summarizes the results. Survey conditions were much better in 1972 than 1971 and the results were much more favorable.

Central district

The Fishery: A total of 2,014,966 salmon were harvested in the Central district in 1972. The catch by species was 11,174 kings, 794,087 sockeye, 61,587 cohos, 537,750 pinks, and 610,368 chums. This was the lowest even-year catch since 1954 and was 38 percent below the even-year average since that time.

One phenomenon occurred in 1972 that tended to hold the catch down in the Central district. Clear water and calm weather conditions prevailed throughout the season causing a reduction in efficiency of gill nets during the 12-hour daylight periods. Observations were made during the season of salmon swimming along the nets and passing around the ends rather than swimming into the nets and being gilled. This condition tended to hold down the harvest and allowed excellent escapement on sockeye salmon. Fishing time was not restricted during 1972, in fact there were several time additions in selected areas of the district.

The 1972 catch by species by date for the Central district is presented in Table 12, and the catch by species since 1954 appears in Table 13 . The king salmon catch of 11,174 was the best since 1961 although still about 4,000 below the average since 1954. The sockeye catch of 794,087 was the highest since 1968 and only about one hundred thousand below the average since 1954. The coho catch of 61,587 was the worst for an even

or odd year, since 1954. The pink harvest of 537,750 was also low, in fact it was the lowest even-year catch since 1954. The 1972 chum catch of 610,368 in the Central district was nearly one hundred thousand above the average for all years since 1954; however, it was ten percent below the even-year average since that time.

In analyzing the above catches in respect to how they relate to long-term averages, one must look at many facets of the 1972 season. The units of active gear, the number of fishing hours allowed, and the unusual clear water conditions experienced were all factors influencing the low even-year catch. The number of active drift boats in 1972 was 457, the lowest since 1966 which is the earliest year we have records for. The number of active set net fishermen, 495, was the lowest for an even year since 1966. (Table 14) The total number of fishing hours for the season was the lowest for an even year in the history of Cook Inlet and only one odd-numbered year, 1971, had less hours allowed. The unusual clear water conditions have already been mentioned and although there is no way of accurately assessing the effect on the salmon harvest, it was unquestionably an influence in holding it down.

There were five emergency orders issued in 1972 which affected the salmon fishery in the Central district. The first opened the Chisik subdistrict and the Northern portion of Iliamna subdistrict to one extra 12-hour period on July 5. This was to allow extra fishing time on the peak of the sockeye run to the lower west side of the district. The Grecian (also Cresent) River, which is the major indicator for this run, had excellent escapement and extra time was warranted. This was the only emergency order put into effect during the major portion of the sockeye run.

The second emergency order allowed an extra 12-hour period on July 26 for the entire gill net area with the justification being good overall sockeye escapement. Effort dropped off sharply after the sockeye run was over and commencing August 2 an extra 12-hour period per week was allowed throughout the district.

There was an excellent late pink run to the Kenai-Kasilof systems and two, 24-hour periods were allowed, one on August 4, and the other on August 7. These were the two final emergency orders issued during the main course of the salmon season in the Central district during 1972.

Field Operations

Escapement: The Kenai and Kasilof River systems are the major spawning systems in the Central district being utilized by all salmon species except chums. These rivers are at present the only systems in the Central district monitored on a daily basis for salmon escapement.

The main streams of both the Kenai and Kasilof rivers are turbid and prior to 1968, escapement into these systems was derived by surveying the clear water spawning areas. This gave only a rough indication at best of escapement plus the surveys could only be accomplished when the fish were on the spawning beds, which was well after the commercial fishing season. The data thus had little use in season management purposes. In 1968 sonar counters were installed in the main stems of both systems. Not only could the counters provide more accurate escapement information but they were located close enough to the fishery so that the information could be used for in-season management. The mechanics of the counters

have caused some problems, particularly in 1971, but as a whole they have proved to be an extremely useful tool. A detailed description of the operation and method of use of the sonar counters is presented by Davis (1971). Details of the 1972 operation can be found in Davis' 1972 Cook Inlet Sockeye Annual Technical Report.

In 1972 a total of 348,261 salmon were enumerated past the Kasilof River counters. Species composition apportioned by the fishwheel catch is given in Table 15 for the Kenai River and Table 16 for the Kasilof River. The sockeye counts for both of these systems were on the high end of the preferred escapement range. The Russian River which is the main spawning system in the Kenai, had a late run escapement of 78,842 sockeye which is about 30,000 above the 50,000 escapement goal. The present desired sockeye escapement ranges are 150,000 to 250,000 (mid-point 200,000) for the Kenai River and 75,000 to 150,000 (mid-point 100,000) for the Kasilof River.

Figures 2 and 3 graphically compare timing of the 1972 run with previous years in the Kenai and Kasilof respectively. The timing of the run into the Kenai was similar to other years except that the bulk of the escapement occurred over a shorter period than normal. The timing into the Kasilof was about 12 days later than normal and 68 percent of the Kasilof escapement came in the three-day period from July 22 to 24.

The surveys conducted on the clear water streams of both the Kenai and Kasilof systems were in general accord with the sonar counts.

Russian River Studies: During 1972, the Russian River weir operation and sampling program was turned over entirely to the Sport Fish Division for funding and operation. Some assistance in planning and weir installation was provided by Commercial Fisheries Division research personnel. Since the

Russian River is one of the major producers of sockeye salmon in the Kenai River Drainage and sockeye salmon from this system undoubtedly are harvested in the commercial fishery the results of the Sport Fish Division work in the system will be presented in this report.

Operation of the weir for adult salmon was essentially the same as it had been since the installation of the weir in 1969. The weir was installed June 15 and operated through August 27. Salmon passing through the weir were enumerated on a daily basis. Fish were observed for the presence of tags and their general condition. Fish were sampled daily for scales and length for routine sampling and age information.

Table 17 shows Russian River sockeye salmon escapements from 1960 to present. The early run escapement which was completed July 29, totaled 9,273 fish. The sport fish harvest of the early run was 3,650. A reasonably low percentage of the fish were scarred, indicating that the 1972 closure imposed on the sport fishery near the confluence of the Russian River and the Kenai River probably had some effect on the quality of the spawning escapement. This closure gave some protection to the fish which were schooled up near the confluence of the two rivers and prior to 1972 had been quite susceptible to the sport fishery.

The late run escapement from July 30 to August 18 amounted to 78,842. This is the highest observed escapement in the 13-year hsitory of enumeration of the run. The sport fish harvest on the late run was 17,280 fish. The total escapement of both early and late runs was 88,115 fish which is the highest total escapement for the Russian River tabulated to date since 1960.

The peak of the early run passed through the weir between July 1 and July 12. Some early fish were still moving through the weir until late July. The late run escapement totaled 78,842 salmon, of which 160 were estimated to be jack salmon. There were also 666 coho and 172 king salmon tabulated through the weir.

Table 17. Russian River sockeye salmon escapements and sport fish catch 1960 - 1972

Year	Early run escapement (thru July 15)	Sport fish census	Late run (July 16 on)	Sport fish census	Total river run	Total escapement
1960	9,115		34,839		43,954	43,954

1962		3,400	55,653	1,300	60,353	55,653
1963	15,311	3,670	51,100	1,390	71,471	66,411
1964	12,782	4,970	46,921	1,885	66,558	59,703
1965	21,776	7,760	21,459	2,940	53,935	43,235
1966	16,915	16,365	34,521	5,455	73,256	51,436
1967	13,706	8,500	49,458	3,638	75,302	63,164
1968	9,204	8,255	48,862	4,445	70,766	58,066
1969	5,000 1/	5,375	30,020 2/	1,075	43,342	35,020
1970	5,451	5,750	28,200 3/	600	40,001	33,651
1971	2,654 4/	2,700	54,429 5/	10,700	70,483	57,083
1972	9,273	3,650	78,842	17,280	109,045	88,115

1960-67 escapement counts are based on tower counts for 15 minutes per hour for 12 hours then skipping 16 hours and counting again 15 minutes per hour for 12 hours and then expanding by 9.33.

1968 early escapement based on 15 minute hour counts for 24 hours and then expanding by 4. Late escapement based on procedures followed in 1960-67.

1/ early escapement is a spawning ground estimate; fish were passing through the weir undetected. Late escapement is a total count - weir made fishproof.

2/ count includes 1,100 sockeye salmon counted in Lower Russian River after weir removal.

3/ 1970 count includes 2,000 estimated at falls after weir removal.

4/ early run through July 27.

5/ does not include fish in falls or mortality data collected from fence in lower river (approximately 10,000 sockeye salmon were unable to ascend the falls and probably did not spawn).

6/ early run through July 29.

Beach Survey: Since 1964 one temporary employee has been assigned the task of driving the east side beach of the Central district from the Kenai River south to Ninilchik. The major objective of this survey is to obtain average catch per unit of effort by species and location, and relay this information to the Homer office. A secondary but equally important function of the beach survey is to act as liason for the Alaska Department of Fish and Game and the east side set net fishermen. The Beach Survey man also assists with scale sampling and sonar operations.

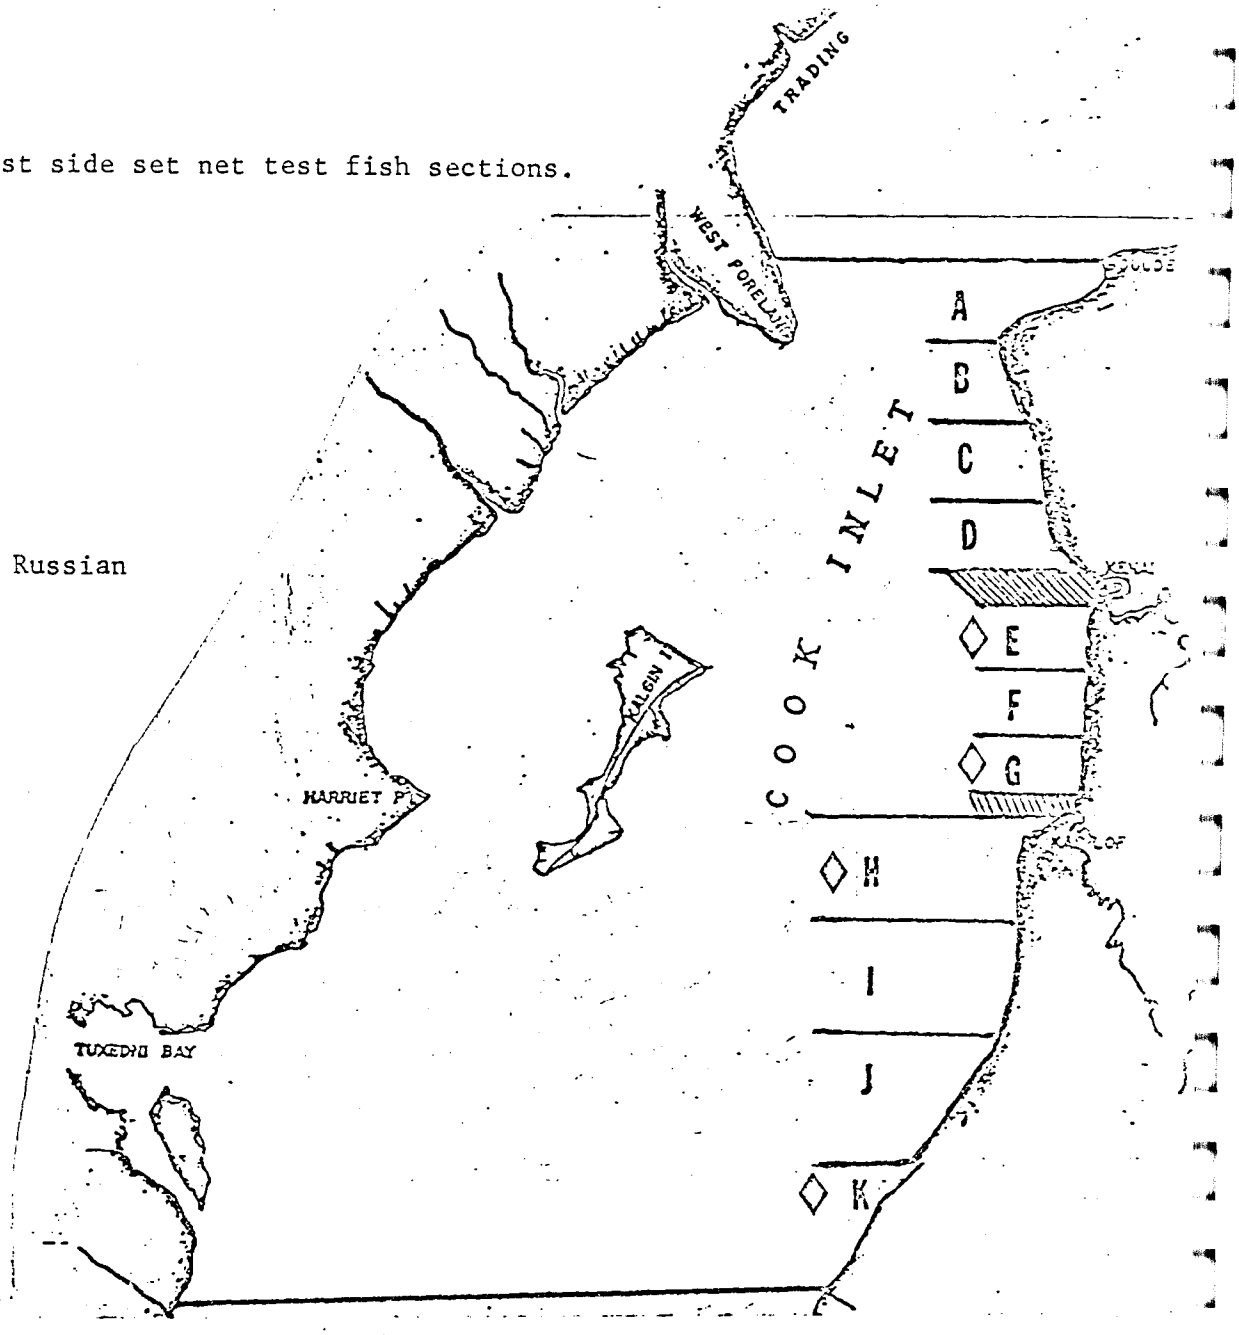
Detailed accounts of the beach surveys can be found in the annual beach survey reports on file in the Homer office.

Test Fishing: After the problems encountered in assessing the run in 1971, it was decided to experiment with different types of test fishing in the Central district to see if this might help in determining timing and species composition at a time when this information would still be useful for management purposes.

Four different test fishing operations were employed in 1972. These were (1) set netting on the east side beaches prior to the regular fishing season, (2) set netting on the east side beaches during the regular season, (3) drift netting during the regular season, and (4) set netting in the Kenai and Kasilof Rivers during the regular season. The drift netting and set netting in the rivers was conducted by Fish and Game personnel.

Set Net Test Fishing: The early test fishing on the east side beaches prior to the season was done to determine the percentage of Russian River bound fish in the early sockeye run. Four sites (Figure 4) were fished on June 11 and again on June 16. Each site was fished until about 100

Figure 4. East side set net test fish sections.



Sections used in early Russian River test fishery

SECTION BOUNDARIES

Section	North Boundary	South Boundary

K	7 miles north of Ninilchik Light	Ninilchik Light

sockeye were caught. If it appeared that a lot of kings were also being taken the fishing was cut short. All sockeye caught were sampled for age, length, and sex, then released if unharmed or sold to the canneries if injured or dead.

The percentage of Russian River bound fish was determined by the fresh water circuli counts of the scales collected from the various sites. Basically early Russian River sockeye are two-check fish with a distinct number of circuli. This characteristic appeared reasonably definitive for the Russian River race of sockeye in previous years.

The table below gives the percentage of Russian River fish found in the test fishery for each site by date.

June 11		June 16	
Site	Percent Bound For Russian River	Site	Percent Bound For Russian River
1	52.8	1	33.3
2	35.4	2	46.6
3	23.7	3	38.9
4	25.9	4	notfished
Ave.	34.5	Ave.	39.6

The test fishery on the east side beaches during the regular season was initiated to determine its usefulness as an indicator of the timing of the various runs of salmon on the east side. The entire set net area on the east side of the Central district was included in the test fishery. This area was divided into 11 sections (see map Figure 4). One fisherman from each section was selected by chance, to test

fish his section for the season. There was an exception to this in Section E during the second test fishery. Due to Section E's proximity to the Kenai River one fisherman fished the northern boundary and one fished the southern boundary.

It was originally planned to have three test fish periods, one each Wednesday, during the month of July. In this way there would be catch information available for the gap between the regular periods on Monday and Friday. However, there was a general fishery on July 26, so no test fishery was held on that date.

The number of nets fished per site was varied between the two test periods. During the first period the test fishermen were allowed to set three 35 fathom nets for four consecutive hours and during the second test period the fishermen were allowed to fish one 35 fathom net for four hours. The fishermen were allowed to select the time they fished.

The results of the two test fish periods are given in Table 18 . Several years of data would have to be compiled for a test fishery of this sort to be useful. Even then with so many variables involved, tide differences, weather, different fishermen, water clarity, etc., the information collected would be difficult if not impossible to analyze on a comparative basis. On top of this, the test fishery created a lot of hard feelings along the beach. No fisherman likes to sit idle while his neighbor is fishing and making money. A test fishery of this sort is not worth the limited amount of information that can be derived from it.

Drift Test Fishing: The drift test fishery was initiated to determine the possibility of mapping the progress of salmon through the Inlet,

spotting any areas of concentration and obtaining species composition. For the drift test fishery in 1972 four fishermen were selected, by chance, from among those qualified to test fish for the entire season. To qualify a fisherman needed to have drift gill netted in Cook Inlet for at least five years. The test fish days were each Wednesday and Sunday in July starting July 5. A general fishery was held on July 26 so there was no test fishery on that date.

Three areas were mapped out for the drift test fishery. These were the waters south of Kalgin Island between east and west rip, the waters east of Kalgin Island between east and west rip, and the waters north of Kalgin Island between east and west rip. Two boats worked the area east of Kalgin Island for the entire season and two boats worked the area south of Kalgin Island for the first four test periods, then the area north of Kalgin Island for the last three test periods.

For each area being worked on a given test period one boat would position itself at the starting point between the east rip and middle rip and the other boat would position itself on the starting point between middle rip and west rip. Fishing would begin at lower low water slack and the boats would work their way north with the tide making at least three sets each about 30 minutes duration. The mean fishing time and the catch by species was recorded for each set. From this the catch per 1,000 fathom minutes was calculated. Table 19 gives this catch by area and date.

The data obtained from the drift test fishery would only be useful on a comparative basis. However, as with the set net fishery, there are so many uncontrollable variables involved that the data would be difficult

to analyze. The clarity of the water from year to year, weather, and sea conditions, tide fluctuations, amount of debris in the Inlet, and the varying skill of the fishermen are some of the variables that would make an intelligent analysis difficult if not impossible.

River Test Fishing: The river set net test fishing program serves as a check against the sonar counters and as a method of determining timing and species composition in the Kenai and Kasilof Rivers. The sites utilized in 1972 were located in the upper intertidal portion of the rivers. The Kenai site was about 1 1/4 miles up river from the Columbia-Wards cannery and the Kasilof site was at Ed Trujillos, about two miles from the mouth.

The sites were fished each high tide from one hour before high water slack to high water slack, with 75 feet of 5 1/8 inch gill net, 12 feet deep. The nets were fished at high water slack to reduce the effect of the river current on the efficiency of the gear. The catch results were computed as catch per 1,000 foot minutes.

Figures 5 and 6 compare the catch index with the sonar counts and the height fluctuation of the tides. The test catches appear to have a much closer relationship to tidal height than to the sonar counts. There are some mechanical problems involved with set netting in the rivers that influences the catch but the basic problem seems to be that there is little relationship between the movement of fish intertidally and their subsequent movement over the sonar counters. This could be due to a milling tendency and/or mixing of stocks at the mouths of the rivers at high tide.

Figure 5. Comparison of river test fish catch, sonar counts, and tidal height, Kenai River, 1972.

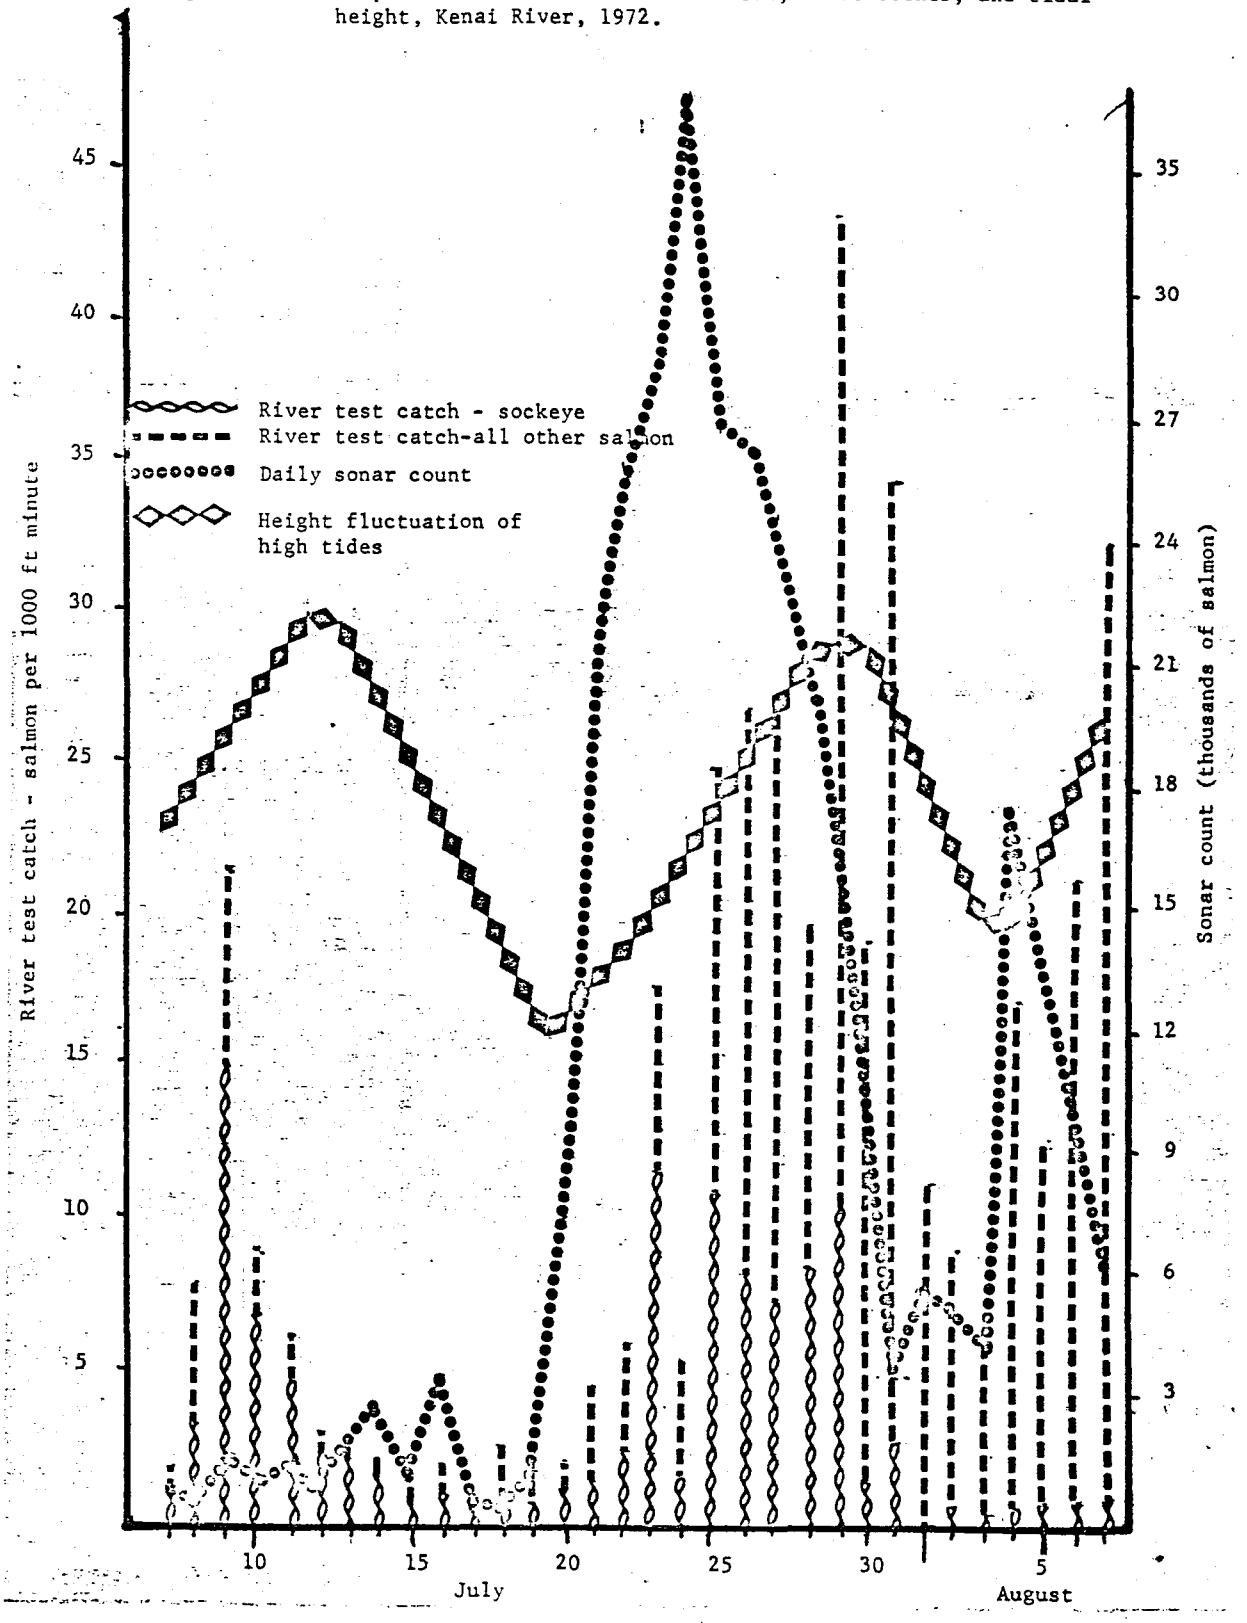

Figure 6. Comparison of river test fish catch, sonar counts, and tidal height, Kasilof River, 1972.

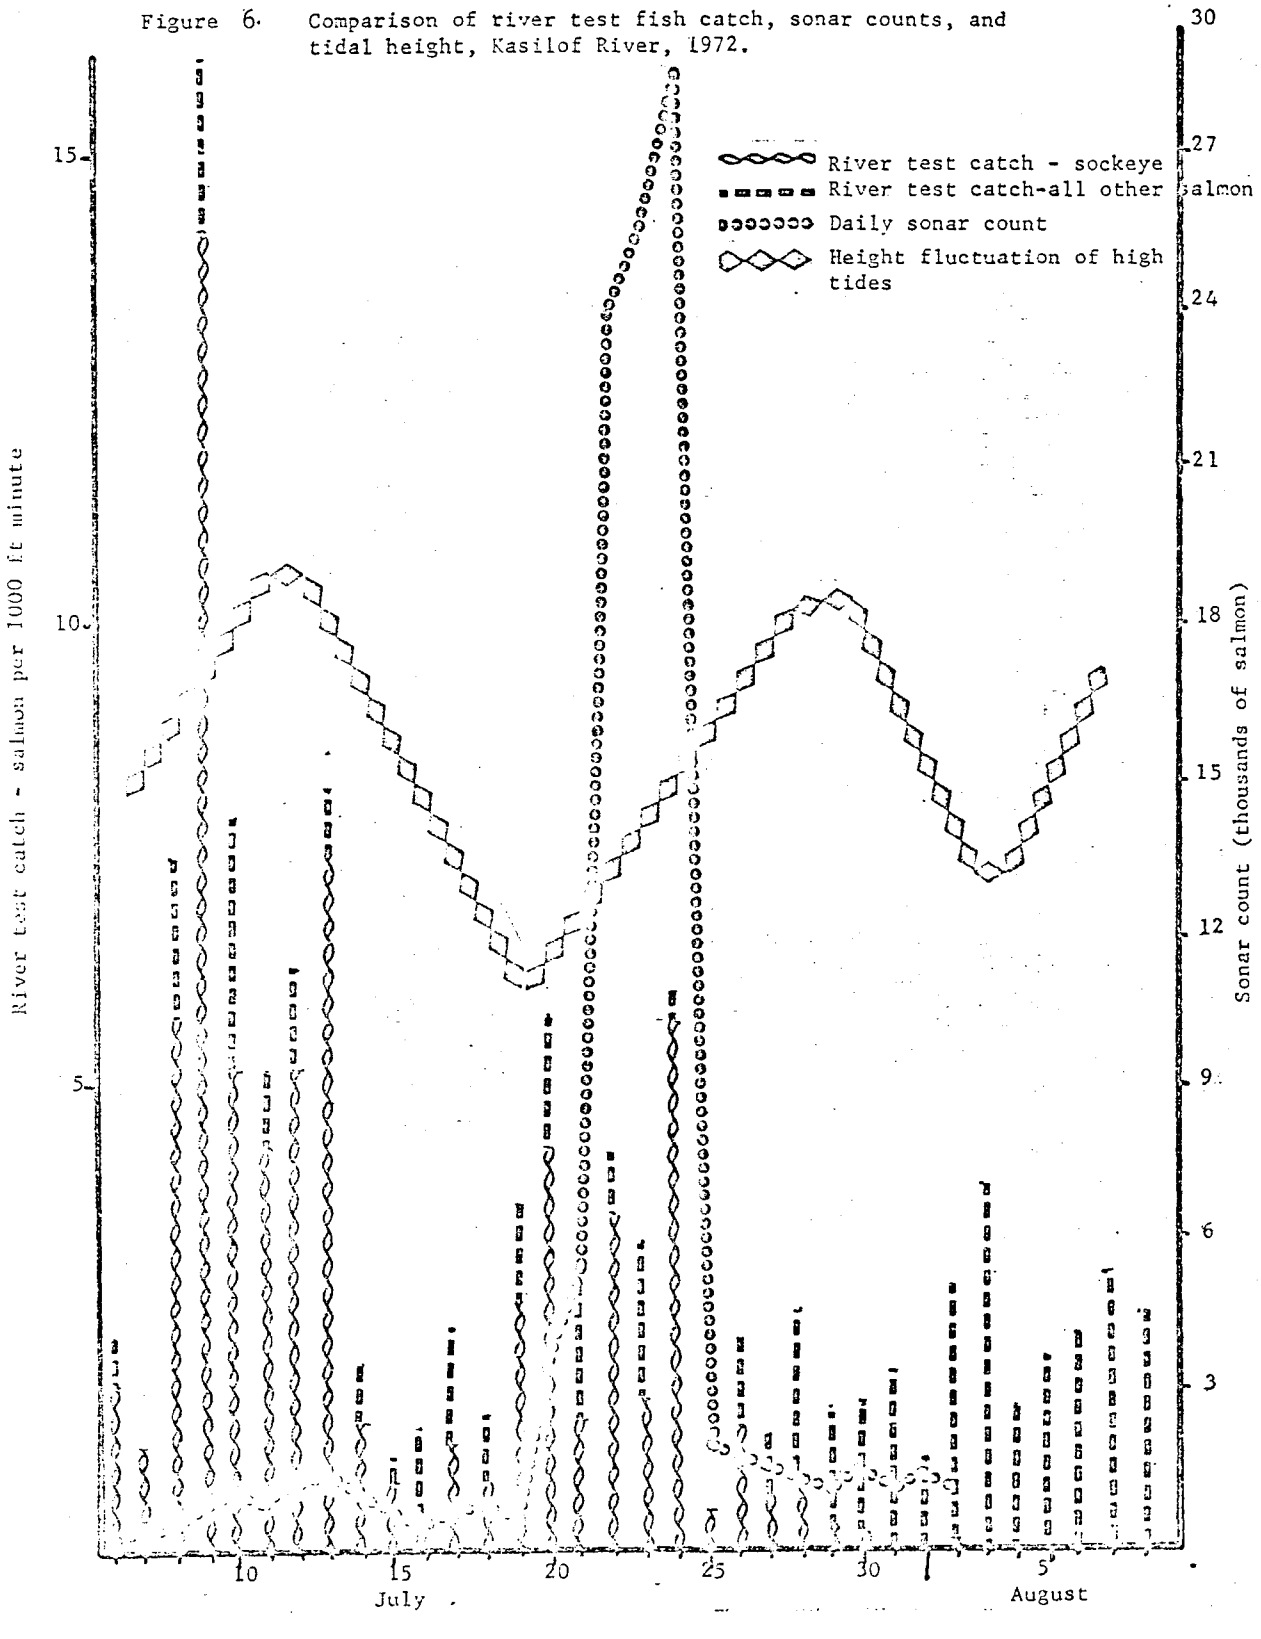

Commercial Catch Sampling: Sockeye salmon taken in the Central district fishery were sampled for age, length, and sex after each fishing period. Samples were taken from both the set net and drift fishery. Table 20 gives the age data for sockeye harvested in the Central district.

It is interesting to note the change in the age composition during the course of the season. In the set net fishery a higher percentage of older larger fish are taken during the early periods and as the fishery progresses the percentage of younger fish increases and the percentage of older sockeye decreases. The drift fishery tends to catch larger fish over the entire season. A more detailed presentation of AWL data appears in Davis' 1972 Cook Inlet Sockeye Annual Technical Report.

APPENDIX B

SUBSISTENCE FISHERY REPORT 1972

A. General Information

1. Description of Area: The Cook Inlet Area includes all waters of Alaska in Cook Inlet and Resurrection Bay north of Cape Douglas and west of Cape Fairfield, including the Barren Islands. (Figure 1)

2. Species Utilized: All five species of pacific salmon are utilized in the Cook Inlet area. Since 1962 cohos have made up 66.2 percent of the catch, sockeye 19.7 percent, pinks 8.4 percent, chums 5.4 percent, and kings 0.2 percent. (Table 1) King crab, tanner crab, dungeness crab, shrimp, smelt, herring, bottom fish, and clams are also utilized for subistence purposes, however, few records are available on degree of utilization. In actuality it is hard to define what constitutes "sport fishing" and what constitutes "subsistence fishing" for the above listed species.

3. Economic Conditions: No figures are available on the average income of those applying for subsistence permits in the Cook Inlet area. It is the personal opinion of the area management biologist that less than five or ten percent of the subsistence fishing in the area is carried out by persons in such financial positions that they actually have a legitimate need of the resource harvested in order to subsist. The type of subsistence fishing found in the Cook Inlet area could more appropriately be classified as recreational or supplemental fishing. Many people regard it as a form of sport

1/ Total salmon catch was 1238, 19 salmon reported as "other".

fishing in which they not only derive recreational benefits but at the same time supplement their food stocks. There are some people in the Cook Inlet area, natives and whites alike, who are, because of either need or personal preference, trying to maintain a "live off the land" life style. To these few "subsistence" fishing may fall into a need category and may play an important part in their means of existing.

B. History of Fishery

1. Methods of Fishing: There are a variety of methods used in the Cook Inlet area as it is a multi-species utilization area.

a. Salmon: Set nets, seines and drift nets are currently used with set nets accounting for about 95 percent of the effort. Since statehood all subsistence salmon fishing has been in conformance with commercial regulations and, therefore, areas open and methods used have been identical to those used in the commercial fishing. Prior to statehood much of the subsistence fishing took place in salmon spawning streams with gear ranging from hook and line to gill nets. Snagging was one of the more popular methods.

b. Shellfish: King crab, tanner crab, dungeness crab and shrimp are all taken with various forms of pots. Most of the fishing takes place at or near the small boat harbors of Homer and Seward. Clams are also taken for subsistence and the method utilized is by clam shovel. The methods currently used for taking shellfish species for subsistence purposes do not differ appreciably from those used prior to statehood.

c. Smelt and Herring: Gill nets are used for taking herring and both gill nets and dip nets have been used in the Cook Inlet area for taking smelt, however, beginning in 1972 dip nets are no longer legal gear for taking smelt for subsistence purposes in the waters of the Kenai Peninsula. There is also a limited amount of hook and line snagging for smelt.

d. Freshwater species: The gear most commonly utilized for freshwater species are small mesh gill nets and seines. In the past, fishwheels and dip nets have also been used in freshwater.

2. Catches and Fishing Effort

a. Salmon: The salmon fishery is the only subsistence fishery for which reliable catch and effort data exists and this data is available only from 1962 through 1972. During these years a total of 3,127 subsistence permits were issued and all but 350 were returned. The total reported salmon catch from 1962 to 1971 is as follows: 102 kings, 8,822 sockeye, 29,604 cohos, 2,449 chums, 3,747 pinks for a total of 44,724 salmon. The numer of permits issued and the total catch by species appears in Table 1 and is depicted in graphic form in Figure 2. The 1972 salmon catch by area appears in Table 2.

b. Smelt: Catch data on smelt is only available for the past two seasons. In 1971 there were 1,387 smelt reported taken and in 1972 the reported catch was 8,542. Most of the effort has taken place along the western shoreline of the Kenai Peninsula and around Turnagain Arm.

The number of permits issued by year since 1969 appear below:

Year	Salt Water	Kenai River	Total
1969	150	194	344
1970	157	393	550
1971	92	*	92
1972	160	*	160

*Smelt permits not required for Kenai River.

c. Shellfish: There are no permits required for taking shellfish and, therefore, no records are available on effort or catch. Almost all of the effort occurs in Kachemak and Resurrection Bays. The Sport Fish division plans a creel survey for the Kachemak Bay shellfish fishery in 1973.

d. Freshwater species: There have been relatively few permits requested for taking freshwater species and most of these have been for Lake Louise and Tyone Lakes. About 90 percent of the catch is whitefish.

3. Management Regulations: The following is a history of subsistence regulations in Cook Inlet from 1943 to 1972.

1943 through 1950

No mention made in Cook Inlet section of commercial fisheries regulations.

1951

First mention in commercial regulations. Required notification of intention to take salmon for personal use, with statement of type of gear to be used, area, time, number of fish to be taken and intended disposition of fish taken.

Fish, Ship, Campbell and Cottonwood Creeks closed to personal use.

1952

No intent to take notification required. More streams closed, including all tributaries to Knik Arm, Willow Creek (tributary to Susitna), Campbell Creek, and all streams and lakes of the Kenai Peninsula that are tributary to Cook Inlet: Provided this shall not apply to fishing with rod, hook and line for personal use.

(Apparently this was the first time many Cook Inlet streams were closed to use of nets for personal use of fish.)

1953

Above regulations same, plus added stipulation that no personal use fishing allowed within 300 feet of weirs and ladders. Snagging was prohibited for the first time.

Also, personal use fishing prohibited within 500 yards of all other streams or lakes except with hand rod, hook and line. Bay limit two (2) per day per person.

And subject to laws regulating commercial fishing 48 hours before and continuing 48 hours after each fishing period. Except for fall season and/or place greater than 25 miles from waters open to commercial fishing . . .

And in Knik Arm where 15 fathom set nets, 100 yards apart, shall be operated prior to August 6, only during hours open to commercial fishing in the Northern district.

1954

Same as 1953 with additional sections that. . . Commercial gear may be used for personal fishing during any fall season. . .

Fishing allowed in Turnagain Arm east of a line between Hope and Indian, and. . .

Fishing allowed more than 5 miles upstream from tidewater on all streams and lakes of Cook Inlet drainage south and west of the Susitna River or south of the town of Homer.

1955

General regulations and. .

Cook Inlet regulations same as 1954.

1956

Same as 1955 with added restrictions. . .

Closed Kenai & Russian Rivers within 300 yards of their confluence (this to 'Sportsmen').

Rod and line. . . limited to take two (2) salmon over 16 inches, per day per person.

1957

General regulations same as 1956.

Cook Inlet about same except for limit on take by rod and line fishermen ('.. not to exceed 10 inches' .. per person per day by hook and line, and not more than two (2) may exceed 16 inches').

1958

General same as 1957 plus. . .

A series of regulations devised to try to curb snagging. . including limiting size hoods and making it illegal to use weights with multiple hooks.

Cook Inlet same as 1957.

1959

General same as 1958.

Cook Inlet--added restrictions that. . . personal use fishing be allowed in the main stem of the Susitna River above the town of Alexander. . with nets less than 30 feet and more than 100 yards from any other set net and from tributary streams--and identified with name and address of owner.

And personal use fishing must be done in conformance with commercial regulations (This closed Knik Arm and Turnagain Arm).

Many Kenai Peninsula streams closed above markers placed from 3 to 5 miles up from mouth (Anchor, Deep Creek, Stariski and many others).

Added closure of Cooper Creek, Little Willow Creek and Montana Creek. . And . . allowed 30 yards of set nets for use in Knik Arm after August 9, also Fish Creek closed July 21 (snaggers harrassing red run).

1960

General same as 1959.

Cook Inlet--personal use fishing to be allowed on Northwest shore Knik Arm. . with nets 90 feet or less and more than 500 yards from terminus of any salmon stream. . and conform to commercial open periods in Northern district. . and identified with name and address of owner.

1961

General same as 1960.

Cook Inlet added open fishing season on clams, crabs and bottom fish. . all in conformance with commercial regulations.

Salmon for subsistence was broken into districts. . apparently this did away with fishing in main stem of Susitna River above Alexander (see subsistence regulations for Northern district 1961).

1962

General regulations added restrictions--personal use fishing must be done by permit only, issued by commissioner. . . limited subsistence fishing catch to individual regional regulations.

Cook Inlet--same as 1961.

1963

General regulations--new regulation--fish other than salmon may be taken at any time in any area of state by any method except by use of explosives or chemicals, except as hereinafter provided or as provided in the Sport Fishing Regulations of the Department.

Cook Inlet--same as 1962.

1964

General same as 1963.

Cook Inlet--new regulation--must have permit for salmon and all catches by species, location and date of catch must be reported. Freshwater species except for trout, grayling, and char may be taken for subsistence purposes via permit and these permits be issued by commissioner or his representative when deemed warranted.

Also not more than 50 salmon be taken per permit and subsistence fishing is prohibited in any area closed to commercial fishing except for parts of Knik Arm.

All districts with the exception of the Outer district, must have name and address of owner on fishing gear. The Outer district regulations were amended to conform with commercial regulations.

Another Cook Inlet regulation was amended--sports fishing licenses required for clams and/or bottom fish and crab pot floats will contain the name of owner. No sex or size limitations on crab.

1965 to 1969

Outside of minor amendments and a few changes in regulations in the different fishing districts, personal use fishing regulations are about the same for that period from 1965 to 1969.

1969 and 1970

Cook Inlet--new regulations--

Restrictions:

(a) Subsistence fishermen taking herring and smelt in the Kenai River must be physically present at all times said net is being fished.

(b) A sport fishing license is required when bottom fish are taken with fishing rod and line.

(c) A sport fishing license is required for the digging of razor clams.

Size Limits: There are no size or sex limitations on crab.

1971

Cook Inlet--new regulations--

Salmon - The subsistence fishery on the Northwest of Knik Arm was deleted.

Smelt - In the Kenai River the length of gill nets may not exceed 20 feet in length.

Smelt may be taken in that portion of the Kenai River from its mouth upstream to the Soldotna bridge from April 1 through May 31.

1972

Cook Inlet--new regulations-- Smelt - Dip nets may not be used for taking smelt in the waters of the Kenai Peninsula.

C. Problem Areas

1. Northwest Shore Knik Arm: This area is no longer a problem as it was closed to subsistence fishing in 1971. The number of permits issued for this area had increased during the mid-60's to a level of 290 during the last two years of the fishery. (1969 and 1970) The reported catch during this period averaged 3,300 salmon (Table 3). The main justification for closing this area was the declining red salmon escapements into Fish Creek which reached a low of 6,233 in 1969.

2. Mud Bay: The problem here appears to be over utilization of available fishing space rather than over-utilization of the resource. Commercial fishing, sport fishing and subsistence fishing all take place in this rather confined area of Kachemak Bay along the northeast

Table 3

Cook Inlet Subsistence salmon fishery
Permits Issued and Total Salmon Catch By District, 1967 - 1972

	Northern 1/		Central		Southern		Eastern

1972	9	52	5	49	170	1,123	5	14

1/ Northern district represents Northwest shore at Knik Arm

side of the Homer Spit. Peak utilization occurs in mid to late August when approximately 10 seine fishermen, 50 subsistence fishermen and several hundred sports fishermen fish this area. The main species being sought are silver salmon and the subsistence catch has averaged about 1,000 since 1967. The commercial catch in the Southerndistrict has averaged 2,800 silvers since 1967 and an estimated 50 percent of these have been taken from Mud Bay proper. Sport harvest figures are not available, however, the average catch since 1967 would probably not exceed 500 fish. Commercial and subsistence harvest figures indicate no decline in abundance of silver stocks in Mud Bay. A tagging study in 1970 indicated the silver stocks of Mud Bay were mostly local stocks bound for upper Kachemak Bay and escapement indicies in this area have been consistent in recent years.

Although there is still no biological justification for closing Mud Bay, the time has perhaps come for closing a portion of Mud Bay to commercial and subsistence fishing.

For several years now proposals have been submitted to the Board of Fish and Game asking for either complete or partial closures of Mud Bay. The commercial fish staff has always opposed these closures on the basis of no biological justification.

Because of the increasing sport fish utilization there was another public proposal submitted to the Board of Fish and Game at the November 1972 meeting by a Homer commercial fisherman which asked for a partial closure of the Mud Bay area. The commercial fish staff supported this proposal, however, it was not passed.

3. Shellfish: Another potential problem is the crab and shrimp pot fisheries which have developed tremendously in the last few years. There is a great volume of gear being fished in the immediate vicinity of the Homer small boat harbor and again, rather than over-utilization of the resource the main problem may be over-utilization of area. Gear is so concentrated in this one area that navigation has been hindered. A regulation may be necessary in the near future to close a section of the bay in the immediate vicinity of the small boat harbor entrance.

D. Recommendations:

1. It is the personal opinion of the area biologist that there is a place for subsistence fishing in Cook Inlet and that it should be continued with some modifications. The 5 or 10 percent of the people who actually have a legitimate need to subsistence fish should not be denied this right just because the fishery has become recreationally orientated. Perhaps a fee could be placed on a subsistence permit or license. This might tend to eliminate some of those who are participating more for recreational reasons than need and yet keep the regulation constitutional. For those

who could show need, through an application for a waiver on the license fee, a special free permit would be granted. An income level would be established similar to that used in the Food Stamp Program and those falling below the established level would be eligible for the free permit. These measures would probably reduce subsistence fishing by 75 percent in the Cook Inlet area and the fishery would again conform with the true meaning of subsistence.

Table 4. Guidelines

COOK INLET SUBSISTENCE SALMON FISHERY, 1972

Salmon may be taken for subsistence purposes under authority of a permit which may be obtained from the local representative of the department.

Each subsistence fisherman taking salmon shall keep accurate records of the catch involved, by species, location caught, date of catch, and other such information as the department may require.

Salmon may be taken for subsistence purposes only by residents.

Identification of fishing gear shall consist of the name and address of the owner and the number of his subsistence permit.

Not more than 50 salmon may be taken under the authority of a subsistence permit.

Only one salmon subsistence permit will be issued to each person during a year.

A set gill net shall not be longer than 35 fathoms in length and 45 meshes in depth.

The operation of each set gill net shall be performed or assisted by the fisherman in whose name it is registered.

No part of a set gill net may be placed or operated within 600 feet of any part of another set gill net.

FISHING SEASONS:

NORTHERN DISTRICT: from 6:00 am July 31 until 6:00 am September 20 during open commercial fishing periods in conformance with all commercial regulations.

NORTH & SOUTH CENTRAL DISTRICTS: from 6:00 am August 18 during open commercial fishing periods in conformance with all commercial regulations.

SOUTHERN DISTRICT: from 6:00 am August 18 during open commercial fishing periods in conformance with all commercial regulations EXCEPT that set gill nets may be used in any beach area open to commercial salmon fishing.

OUTER DISTRICT: in conformance with commercial regulations.

EASTERN DISTRICT: from June 1 through June 30 during open commercial fishing periods in conformance with all commercial regulations EXCEPT that set gill nets may be used in any beach area open to commercial salmon fishing.

LIST OF APPENDIX TABLES CONTINUED

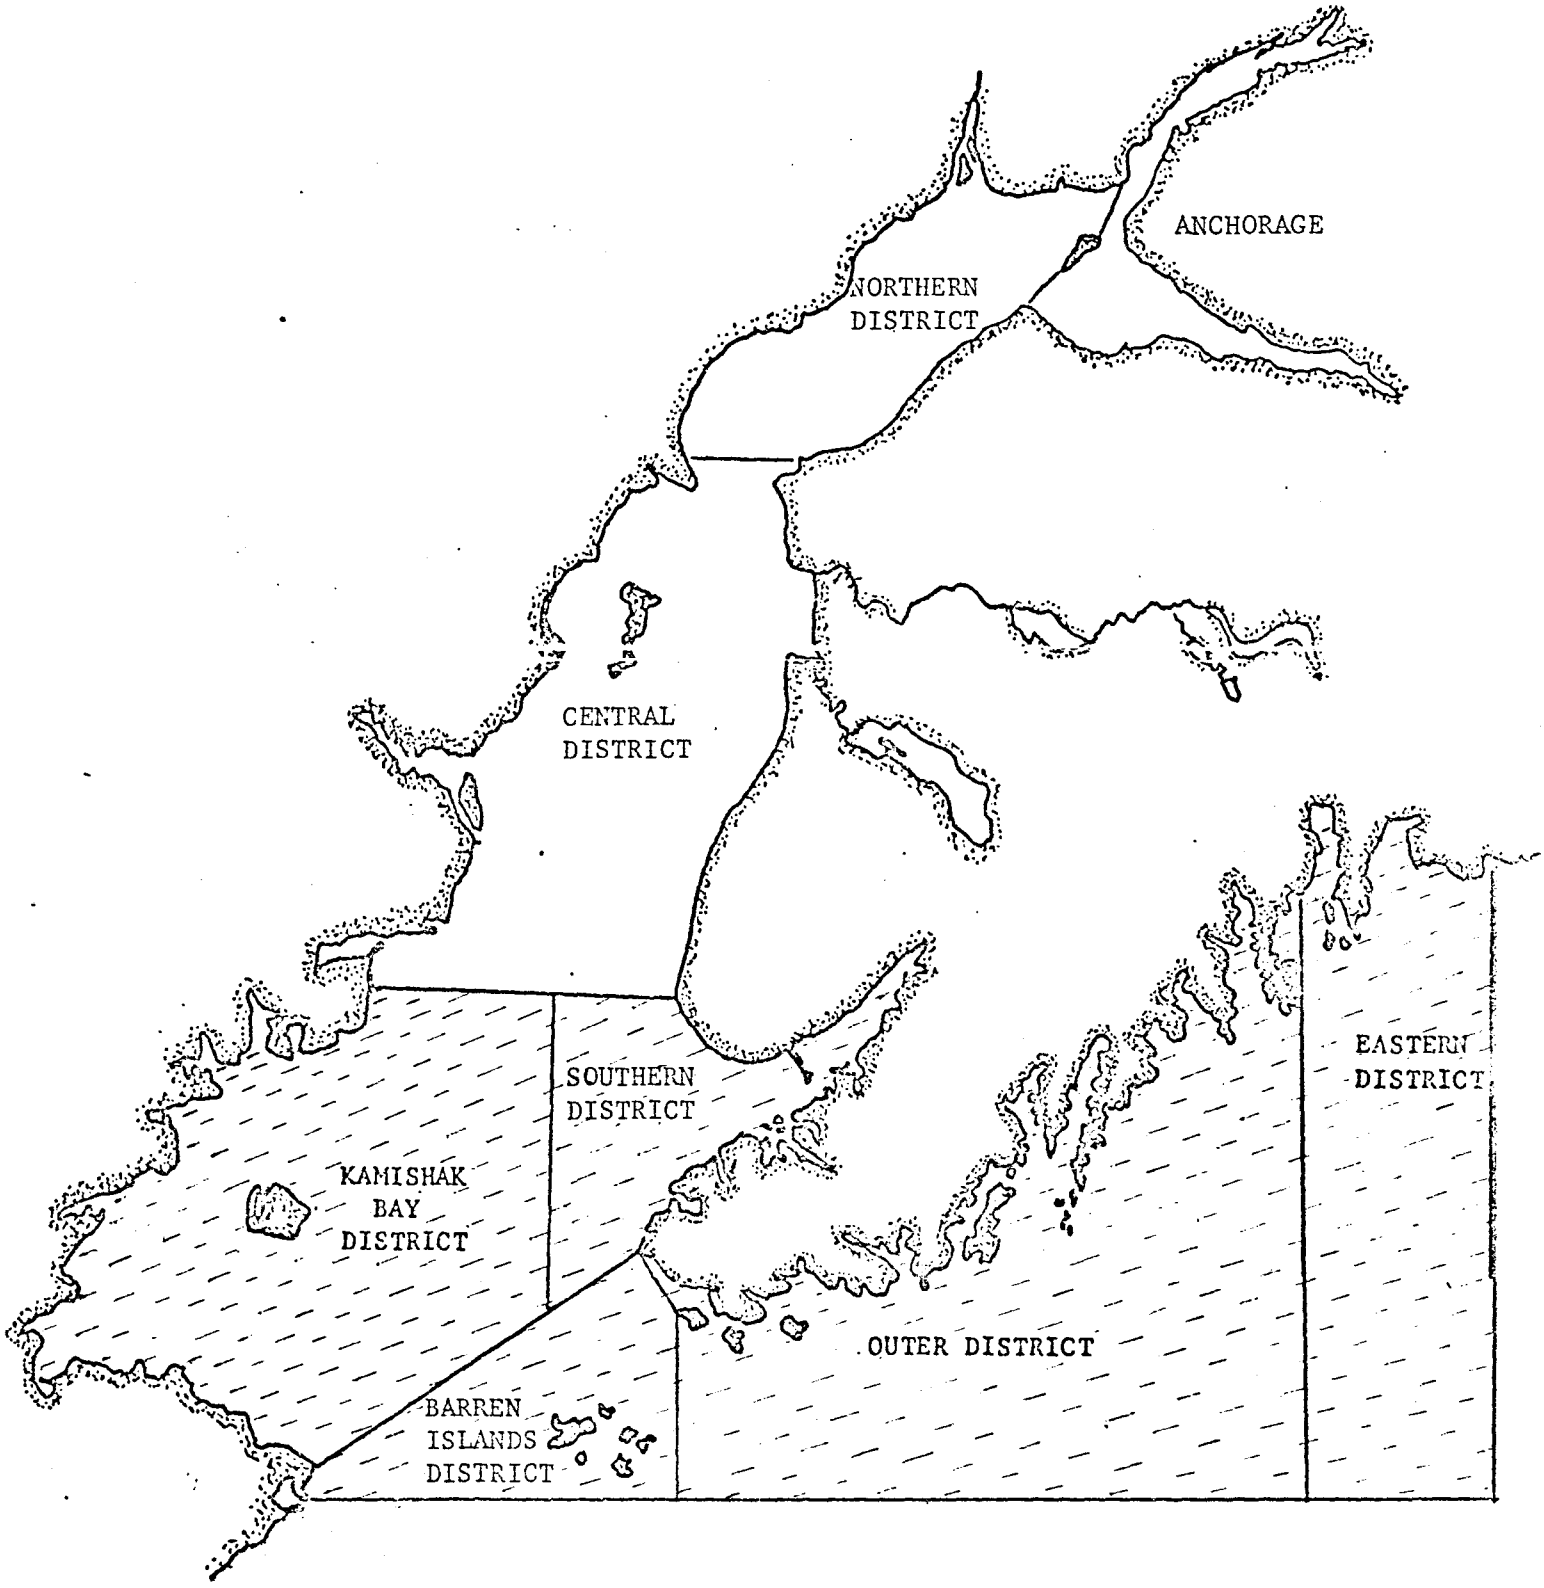
INTRODUCTION

The Southern, Kamishak, Barren Islands, Outer and Eastern districts of the Cook Inlet management area include all waters south of the latitude of Anchor Point north of Cape Douglas and west of Cape Fairfield, including the Barren Islands, southern Cook Inlet, the outer Kenai Peninsula and Resurrection Bay (Figure 1).

With the exception of razor clams practically all shellfish harvested in the Cook Inlet area are from these districts. Trawl and pot caught shrimp, king, tanner and dungeness crabs are the primary commercial species. These shellfish are also harvested by subsistence/sport fishermen. In addition, cockles, scallops and various hard shelled and soft shelled clams are utilized by subsistence/sport fishermen.

The five North American Pacific species of salmon are of commercial importance. Pink salmon are the "bread and butter" salmon for the area as a whole. Salmon are taken commercially by seines and set nets in the Southern district and by seines only in the other districts. Herring, halibut, cod, rockfish, pollock, smelt and other miscellaneous finfish are also taken by commercial and subsistence/sport fishermen.

Figure 1 Cook Inlet commercial fisheries management area



SHRIMP

Generally, 99 percent of the Cook Inlet shrimp catch is taken in the Southern district. The catch for 1972 was 5.5 million pounds. Table 1 shows the 1972 catch by month and number of vessels participating. The 1972 catch was similar to that of 1971 and slightly lower than the 1970 catch. Shrimp landings in pounds since 1960 are shown in Appendix Table 1.

Trawls

Three local boats usually fish the entire season. Two additional boats fished the fall season in 1972. A total of 438 landings were made in 1972 compared to 560 in 1971 and 533 in 1970. (Appendix Table 2) Catches per drag hour since July, 1969 are shown in Appendix Table 3.

Pots

Pot shrimp catches have fluctuated greatly over the years, ranging from 131 pounds in 1969 to the record 171 thousand pounds in 1972 (Appendix Table 4). Effort also varies. A strong market and good prices encouraged eleven vessels to participate in the shrimp pot fishery in 1972, seven on a regular basis.

KING CRAB

1972 Season

The 1972 Cook Inlet king crab harvest of 4.6 million pounds exceeded the 1971 catch by .5 million pounds and was the highest on record since 1964.

Table 1. Cook Inlet shrimp catches, 1972

Pounds and Number of Vessels

Month	Trawls	Number of Vessels	Pots	Number of Vessels	Trawls and Pots Total Pounds
January	405,730	3	1,494	1	407,224
February	641,653	4	1,463	1	643,116
March	170,868	3	14,879	11	185,747
April	77,133	3	7,879	3	85,012
May	77,318	4	7,994	4	85,312
June	539,482	5	23,211	4	562,693
July	544,454	4	24,191	4	568,645
August	569,364	3	11,752	4	581,116
September	471,921	2	16,241	6	488,162
October	651,547	3	3,242	3	654,789
November	618,781	3	29,288	6	648,069
December	608,930	5	29,752	10	638,682
Total	5,377,181	5	171,386	11	5,548,567

The Southern district, which includes Kachemak Bay, accounted for 1.9 million pounds and the total for all other districts was 2.7 million pounds. The 1972 king crab catch by district, by month is shown in Table 2. The annual catch by district, 1951-1972, is shown in Appendix Table 5.

Effort, as measured by number of landings, was greater in the Southern district during 1972 than in any other district. A total of 1,120 landings were made which was 263 more than in 1971. In the Kamishak and Outer districts there was less effort and 119 landings were made as compared to 134 landings in 1971. In the Southern district there were 236 crab per landing and in the Kamishak district the crab per landing figure was 2,733, the highest on record. Appendix Table 6 shows the landings by year since 1960. The approximate value to the fishermen for king crab during the calendar year was 1.6 million dollars, a record high (Appendix Table 7).

A significant increase in the abundance of recruit size king crab was observed in both the Southern and Kamishak districts. This was expected as a strong year class was observed during catch composition surveys and other research studies in the past two years. This strong year class molted into legal sized crab in the spring of 1972 and they accounted in part for the increased 1972 catch. In the Southern district 56 percent of the crab harvested in the summer fishery (August-December) were recruits while in the Kamishak and Outer districts 43 percent were recruits. In the winter fishery (January-March) 31 percent of the harvest were recruits in the Southern district and 34 percent in the Kamishak and Outer districts (Table 3 and Figure 2). Comparative size composition of commercially caught king crab taken in 1963 and in recent years is shown in Appendix Table 8.

1972-1973 Quota Period

The king crab season and quota period in Cook Inlet runs from August 1 to March 31. The quota in the Southern district is 2.0 million pounds while all other districts have a 3.5 million pound quota. In April, 1972 the basic season was lengthened by one month and the outside quota (Kamishak, Barren Islands, Outer and Eastern districts combined) was increased by 1.0 million pounds. Data indicate that catches were approximately 400,000 pounds short of the quota in the Southern district and 500,000 short in all other districts combined for the 1972-73 season. Falling below the quota does not indicate a decline in the crab stocks as all biological indicators looked good. There are three main reasons for the catch falling short of the quota. (1) Due to the increased price on tanner crab many fishermen concentrated their efforts on tanners and although they still made landings on king crab, these were only incidental to the tanner catch. The increased effort on tanners, which tend to abide separately from king crab, had the effect of diluting the potential effort on king crab. (2) Severe ice conditions in the Kamishak district during February and March, 1973 prevented boats from fishing this area until the last week of the season. Had the ice gone out of this area earlier, the outside quota would likely have been reached. (3) The total of January and February catches from the Southern district have tended to be lower during the odd numbered years than during the preceding even numbered years since 1964 (Table 4). The reason for this pattern is not known. Perhaps every other year molting and mating migration patterns of the larger male king crab or biennial cyclic abundance of food supplies may influence this pattern. The total catches recorded for January and February of 1974 may be used to predict the expected total catch for January and February of 1975 if

Table 4 Relationship between total of January and February king crab catches for alternate years in the Southern District of Cook Inlet 1964 - 1973

		Odd Years (X)	Even Years (Y)		$(X-\bar{X})$	$(Y-\bar{Y})$	$(X-\bar{X})(Y-\bar{Y})$	$(X-\bar{X})^2$	$(Y-\bar{Y})^2$
		catches in 1,000 pounds							
1.	(65)	146	320	(64)	- 64	- 60	3,840	4,096	3,600
2.	(67)	162	371	(66)	- 48	- 9	432	2,304	81
3.	(69)	108	237	(68)	-102	-143	14,586	10,404	20,449
4.	(71)	236	270	(70)	+ 26	-110	-2,860	676	12,100
5.	(73)	396	702	(72)	+186	+322	59,892	34,596	103,684
TOTALS		1,048	1,900				75,890	52,076	139,914

$$\bar{X} = \frac{1048}{5} = 209.6 \qquad \bar{Y} = \frac{1900}{5} = 380.0 \qquad byx = \frac{\Sigma(X-\bar{X})(Y-\bar{Y})}{\Sigma(X-\bar{X})^2} = \frac{75890}{52076} = \underline{\underline{1.457}}$$

$$bxy = \frac{\Sigma(X-\bar{X}))Y-\bar{Y})}{\Sigma(Y-\bar{Y})^2} = \frac{75890}{139914} = \underline{\underline{0.542}} \qquad ay = \bar{Y}-byx\bar{X} - 380.0 - (1.457)(209.6) = 74.61$$

$$ax = \bar{X}-bxy\,\bar{Y} = 209.6 - (0.542)(380.0) = 3.64$$

$$Y = byxX + ay = (1.457X + 74.61)(10^3)$$

$$X = bxyY + ax = ((0.542Y + 3.64)(10^3)$$

$$\text{Correlation Coefficient} = r = \sqrt{bxybyx} = \sqrt{(0.542)(1.457} = \sqrt{.7896} = 0.8886 \approx 0.89$$

the correlation between even and odd year catches is valid. It is possible that the 1974 catches will show a breaking point, either significantly higher or significantly lower catches than in other even years for January and February.

Each year, beginning in early February, biologists accompany commercial king crab boats to the fishing grounds to determine catch composition and timing of the reproductive cycle. The closing date of the king crab season is regulated based upon biological findings. In early 1973, because there was no fishery in the Kamishak district until the last week in March, biological efforts were concentrated in the Southern district, or the Kachemak Bay area. By mid-March molting of all king crab was well under way and egg hatching had started. By March 16, 62 percent of sublegal size and 15 percent of legal size crab were in new shell condition. By this same date, 7 percent of the female crab had completed hatching and had molted. For these reasons the Southern district was closed on March 22, ten days earlier than the automatic closing date. After the season closed most fishermen converted their gear for tanner crab and moved their pots out of areas where king crab were highly concentrated. As a result of this, handling of soft shell and female king crab was reduced.

During the last week of March 1973 three boats dropped some gear in the Kamishak district northeast of Augustine Island. They immediately located good concentrations of king crab and a request for an extension was made. The request had some merit since ice conditions had prevented fishing activity earlier and there were still 500,000 pounds to be taken on the quota. However, after examining data, it was evident that the molting and reproductive period was under way. Although only one percent of the legal size males and females had molted by March 29, 85 percent of the sublegal males had molted

and were already in new shell condition. Also, 56 percent of the crab being handled were females and egg hatching had begun. For these reasons, an extension of the calendar season was denied. Results of king crab composition surveys are shown in Table 5.

TANNER CRAB

The 1972 tanner crab catch in Cook Inlet was the highest on record since the fishery developed in 1968. The catch totaled 4.8 million pounds in 1972, compared to 2.1 million pounds in 1971, 1.3 million in 1970, 1.5 million in 1969 and 165 thousand pounds in 1968. Relatively higher prices ($.17 per pound live weight) encouraged additional effort. Forty-three boats delivered tanners from Cook Inlet in 1972, compared to 40 boats in 1971 and 25 boats in 1970. The 1972 landings totaled 956 compared to 613 in 1971 and 314 in 1970. The 1972 catch by area and pounds is shown in Table 6. The catch by month, number of boats fishing each month, the number of landings and the average weights each month for 1972 are shown in Table 7.

The average weight of tanner crab in the commercial catch during 1972 was 2.5 pounds, similar to the 2.4 pounds for 1971 and 2.9 pounds in 1970. The annual catch, the number of landings, number of vessels engaged in the fishery and the average weights since 1968 are given in Appendix Table 9.

In addition to monitoring the commercial catch, carapace width frequencies are collected (Figure 3). Catch composition surveys on the fishing grounds are made to collect pertinent data. This data will be summarized in a separate data report, which will be published as an appendix to a future area management report.

DUNGENESS CRAB

The total 1972 dungeness crab harvest in Cook Inlet was 38,930 pounds, less than half the 1971 catch of 96,846 pounds. The 1970 harvest was 208,577 pounds. The 1972 monthly catch in pounds and number of vessels fishing is given in Table 8.

The dungeness catch by month since 1966 appears in Appendix Table 10 and the total catches since 1961 are shown in Appendix Table 11.

SHELLFISH SUBSISTENCE

King, tanner and dungeness crab are all harvested to some degree by subsistence/sport fishermen. Shrimp, primarily coon-stripe, are taken using pots and ring nets.

Cockles, scallops, other hard shelled and soft shelled clams are also utilized by the subsistence/sport fishermen. Most of this activity takes place in Kachemak Bay. The amount of effort and total harvest has not been documented. The amount of man-days spent in these activities is considerable and increasing each year. The actual catch is insignificant compared to the commercial shellfish take but it is of economic (tourism) and of personal importance to those involved.

SALMON

Overview: Southern, Outer, Kamishak and Eastern districts - 1972

The 1972 salmon catch of 164.3 thousand (0.1 kings, 57.9 reds, 2.2 cohos, 28.6 pinks, 75.5 chums) was the second poorest on record since 1954. Appendix

1/ Incidental catches.

Table 12 shows catches by species and district since 1954. The 1972 catch by primary species by district and week for three districts appears in Table 9. The pink salmon catch by gear since 1960 is shown in Appendix Table 13. Estimated pink salmon escapements, by system, for the Southern and Outer districts since 1962 are given in Appendix Table 14. Ground stream survey results from the Southern district in 1972 are shown in Table 10. Ground stream survey results from the Outer district in 1972 are shown in Table 11. Aerial surveys of the Kamishak district from 1965-1972 are given in Appendix Table 15.

Southern district

The total salmon catch for the Southern district in 1972 was 46,759 fish and accounted for only 1.9 percent of the total Cook Inlet catch. This district catch for 1972 was the lowest on record for the years 1954-1972 (Appendix Table 16).

Pink salmon have always been the major species in the Southern district making up an average of 81 percent of the catch since 1954. The 1972 pink salmon catch of 9,126 fish was by far the lowest recorded for this 19-year period accounting for 20 percent of the total district catch. Red salmon have contributed an average of 7 percent of the catch. In 1972, a good red catch of 31,345, the second highest recorded, contributed 67 percent of the catch. The coho catch of 1,283 was about one-third of the average for this species. The chum catch of 4,936 was far below the 19-year average annual catch of 23,000 fish.

A more intensive management system went into effect in 1971 and this contributed to the lower catches in 1971 and 1972. Instead of a set opening date for seine gear in early June, which has been the practice since

the early sixties, the 1971 and 1972 seine seasons were opened by field announcement. This technique is similar to that used in the Outer district where individual runs are allowed to build up to a point where some escapement is assured before opening. The initial seine season opening was on July 28, 1972. The set gill net season opened on June 5. Two, 24-hour periods per week were fished. On July 31, the entire Southern district was closed to commercial salmon fishing. On August 21 a portion of the Southern district, English Bay and Port Graham, was re-opened for one, 48-hour period. Mud Bay was also opened on August 21 and on September 7 the entire Southern district was closed.

The overall pink escapement into the Southern district was poor with 23,500 total fish for the four major study streams. Humpy Creek had an escapement of 13,800; Tutka, 1,500; Seldovia, 5,800; and Port Graham, 2,400.

Kamishak district

The total 1972 Kamishak district salmon catch was 26,794 fish, approximately half the average catch for this district since 1954. The chum catch of 26,374 represents over 98 percent of the catch. The catch by species since 1954 appears in Appendix Table 17.

The first opening in the Kamishak district was on June 29 and opened everything south of Nordyke Island except McNeil River Lagoon. This same area closed on July 28. On July 29, Bruin Bay was opened and on August 10 that portion of the Kamishak district north of Ursus Head was opened. On August 21 Ursus Cove and Rocky Cove were opened.

Escapement surveys are shown in the appendix.

Outer district

The total salmon catch for the Outer district in 1972 was 70,942, fourth from the lowest on record for this district since 1954 (Appendix Table 18).

The pink catch of 1,005 was the lowest on record, most of the return was kept for escapement. The next lowest catch was 21,816 pink salmon in 1965. The chum salmon catch was fair with 43,490 fish caught, 19-year average = 81,701. The red salmon catch of 26,423 was the bright spot, the highest catch on record for the 19-year period. The next highest catch of reds was 12,595 in 1961.

The Outer district is regulated by field openings and has been since the early sixties. The first opening was on July 6 when the area from Harrington Point east to the boundary of the Eastern district was opened. The opening was justified by a good showing of red salmon in the Desire Lake, Delight Lake and Aialik systems. This portion of the Outer district was closed on August 2.

The second opening occurred at the western end of the Outer district when Dogfish Bay was opened for seines on July 28. This Bay was closed on July 31 and re-opened for a 48-hour period on August 21, 1972, and for another 48 hours on August 24. A major portion of the Outer district was not open to commercial seine fishing. Even so, the total pink salmon escapement in the major study streams in 1972 was 19,900, which was poor. Port Dick received 10,000 pinks, the lowest recorded escapement for the period 1962-1972. Windy Right and Windy Left received 100 and 400 respectively. Rocky River received 8,100 and Island Creek 1,700, all considerably short of adequate pink salmon escapements.

Eastern district

The total salmon catch from the Eastern district in 1972 was 19,930 fish. The average catch for the years 1954-1972 is about 27,000 fish (Appendix Table 19).

The 1972 catch of 18,190 pink salmon comprised 91 percent of the catch.

The Eastern district was opened by field announcement on May 15 to seine and drift gill nets. On June 17 the season was closed for drift gill nets and on August 7 it was closed to seining.

HERRING

Herring Roe Fishery

Compared with the years since 1969 when herring fishing for roe began in Cook Inlet, 1972 was a dismal failure as far as the catch is concerned. A total of 95 tons were taken in Resurrection Bay and one ton was landed from Kachemak Bay (Appendix Tables 20, 21, 22, 23).

There are several factors which could have contributed to the poor season. One definite factor in Resurrection Bay was the Seward small boat harbor being closed to commercial herring fishing for the first time. Previously most of the herring taken in Resurrection Bay came from the small boat harbor and with the closing of the harbor herring became extremely difficult to locate and catch. The Viking Queen, which was equipped with Simrad gear, made several runs around Resurrection Bay looking for herring with no success. The most effective way herring was taken in the Bay in 1972 was during the ebb tide when some of the herring in the boat harbor would move out and be captured by boats waiting at the entrance.

Another possible reason for the lack of herring might be the very cold spring experienced in 1972. Water temperatures in the small boat harbor did

not reach 40° F until May 8 and the first catches didn't occur until May 12. Normally the water temperature hits 40° F during the third week in April. In 1970, which had a comparatively mild spring, the first catches occurred on April 20. This was the second consecutive year that had a very cold spring and the results were the same, relatively small numbers of fish and late spawning.

Three processors handled herring in Seward during 1972; Alaska Scallop, Whitney Fidalgo and Seward Fisheries. Alaska Scallop processed Prince William Sound herring only. Whitney Fidalgo did not process in Seward but shipped their herring to Anchorage for processing or shipment elsewhere. Seward Fisheries processed both Prince William Sound and Resurrection Bay herring in Seward.

All herring processed in Seward were processed for roe only with the remainder of the fish being discarded. Whitney Fidaglo reported that a good portion of their herring were shipped to Seattle for roe processing with the rest of the fish being converted into pet food.

Biological samples of the Resurrection Bay fishery collected in 1972 show good representation in the 1967, 1968 and 1969 year classes and a continued increase in weight and length since the first sample in 1970. The main reason for the increases in weight and length is the percentage representation of older fish. In 1970, 29.6 percent of the sample was older than age III and only 8.2 percent age V or older. In 1971, 56.4 percent were older than age III and 15.7 percent were age V or older. In 1972, 59.2 percent were older than age III and 23.5 percent were age V or older. All this points to an older and perhaps healthy population, however, the number of fish returning to spawn in Resurrection Bay during the last two years has been below 1970 levels. The reason for the poor 1972 run could be

related to low water temperatures during the spawning period, however, there is also the possibility of poor recruitment into the fishery (Appendix Table 24).

Spawn on Kelp Fishery

There was no spawn on kelp fishery in Cook Inlet during 1972, however, an interesting attempt was made which is worth noting.

Seward Fisheries imported from Japan an unidentified species of kelp. Presumably, the kelp was of the variety that the Japanese savor most. It came in the form of dried strips three inches wide and about two feet long. There were 1,200 of these strips in all. The idea was to tie the strips on a line and suspend the line between two floats in an area where the herring were spawning in hopes that the herring would spawn on the kelp. A permit was obtained from the Commissioner to place 100 of these strips in the boat harbor on an experimental basis only with the remaining strips to be placed in Resurrection Bay outside the small boat harbor. Seward Fisheries was to choose the outside locations. The strips were prepared, first by soaking in a brine solution and then in straight sea water. The prepared kelp was then tied to a halibut line and hung on the dock in hopes that spawning herring would make use of it.

Unfortunately, no spawning herring were found. The kelp fermented and the project was abandoned.

HALIBUT

The halibut fishery is regulated by the International Pacific Halibut Commission. Each halibut management area overlaps and includes several state management areas and catch records from discrete state management areas (Cook Inlet, Kodiak, etc.) are not available.

Halibut are caught in every district of Cook Inlet covered by this report (Southern, Kamishak, Barren Islands, Outer and Eastern). Records of halibut landings delivered to Cook Inlet processors are maintained. The 1972 season opened on May 15 and closed on September 14 in Area 3A with total deliveries of 6.37 million pounds of halibut.

MISCELLANEOUS FINFISH

Various finfish species comprise a small but potentially important part of Cook Inlet commercial fishing activity. These species will become of more importance as markets develop and demand increases. The primary producing areas at the present time are the Eastern and Outer districts and adjacent Gulf of Alaska waters. In 1972, 49,602 pounds of Pacific or "grey" cod (Gadus), 1,152 pounds of sable fish or "black" cod (Anaplopoma), 112 pounds of ling cod (Ophiodon), 6,989 pounds of rockfish or "red snappers" (Sebastodes), 1,210 pounds of flounders (primarily Platichtys) and 797 pounds of Dolly Varden (Savelinus) were landed for a total of 59,862 pounds.

FINFISH SUBSISTENCE

The most popular finfishes for subsistence utilization are the salmon. An area-wide permit is required with a 50 salmon limit for each permittee. Only Alaskan residents are allowed to subsistence fish for salmon. Each permittee is required to file a catch report after the season. In general, salmon may be taken for subsistence in conformance with open commercial fishing periods with equivalent gear to that used in the commercial fishery. Calendar date openings are also used for regulation of the subsistence salmon fishery. Records are kept area wide and total catches are given in the overall Cook Inlet report. Of the five districts covered by this report only the Southern and Eastern districts have bonifide subsistence fisheries for salmon. Subsistence catches by species for 1972 are given in Table 12.

Herring, smelt, halibut and incidental catches of miscellaneous finfish are also utilized for subsistence.

Island	15.0	3.6	30.0	.5	7.0	.5	4.3	.1	5.5	.1	1.7	6.2
Total [3/]	466	103	270	142	252	123	196	115	190	254	44	195

[1/] Weir count.

[2/] Escapement estimates were derived from peak counts or calculated from counts made throughout the spawning season. When series counts were available the total fish/days was divided by average stream life (2.5 weeks) to estimate total escapement.

[3/] Rounded to nearest thousand.
